Remarks

ON

A COMMUNICATION BETWEEN THE TWO VENTRICLES OF THE HEART OCCUPYING AN UNUSUAL SITUATION.

By T WARDROP GRIFFITH, M D Aberd, F R C P Lond,

PROFESSOR OF MEDICINE, UNIVERSITY OF LEEDS HONORARY PHYSICIAN TO THE GENERAL INFIRMARY AT LEEDS

The usual situation where one meets with a communication between the two ventricles of the heart is that occupied in the normal condition by the pars membranacea septi The specimen I desire to put on record is one of that small class in which the communication is between the conus arteriosus or infundibular part of the right ventricle on the one hand and the aortic vestibule on the other

The patient, a man aged 30 years, was under the care of Sir Clifford Allbutt in the General Infirmary at Leeds, and died there in April, 1879 The clinical notes of the case cannot be traced, but the post mortem examination was made by the late Dr Jacob, who was then the house physician, and his notes state that the heart was enlarged and weighed 19½ oz. He also mentioned the unusual position of the aperture When, some 12 years ago, I was making a systematic examination of the section in our museum dealing with diseases of the heart, I discovered that this specimen had not been put on record in any of the journals I therefore got permission from Dr Allbutt, as he then was, to show the specimen at the Anatomical Society of Great Britain and Ireland and to publish a description of it At the meeting of the society which was held in Edinburgh in 1907 I gave an account of the specimen and discussed its meaning, giving the explanation which I now put on record

Description of Specimen

In the preparation of the specimen for display in the museum the outer part of each ventricle and auricle has been removed One can see, however, that there must have been considerable hypertrophy of the walls of all the chambers The remains of the mitral and tricuspid valves are normal, there is a valvular patency of the foramen ovale

The long dimension of the abnormal aperture in the ventricular septum would, in the natural position of the heart be almost vertical As seen from the left side (Fig 1) it is situated immediately below and in front of the anterior segment of the aortic valve[1] with the middle three fifths of which its longer dimension is co extensive It measures three quarters of an inch in length by one fifth of an inch in width Its anterior and lower boundary is rounded and concave and is formed by the free margin of the thick fleshy infundibular part of the septum of the ventricles The endocardium lining this margin and for some distance below the aperture on each aspect of the septum is thickened and opaque On the left side especially the endocardium is particularly thick and fibrous and this thickening ends below by a singularly sharp and abrupt edge On the free margin of the septum there are also some vegetations indicative of recent endocarditis The aperture is bounded above and behind by the anterior aortic segment

As seen from the right ventricle (Fig 2) the aperture opens into the conus or infundibular part of that cavity Here it is bounded below and in front by the concave margin of the septum already mentioned, above and behind it is bounded by the anterior segment of the aortic valve, which, in consequence of the deficiency in the septum, is visible from the right ventricle Not only is this segment of the aortic valve visible from the right ventricle, but it projects into that chamber forming an aneurysmal dilatation of about the size of a small hazel nut, which separates the aperture from the antero right pulmonary segment The portion of the valve entering into this dilatation is thinned out and is much less substantial than the rest of the segment At the summit of the dilatation there are two apertures about a fifth and a sixth of an inch respectively in diameter These have projecting margins fringed with recent vegetations

There is some general thickening of the aortic valve segments, the convex aspect of the anterior segment is roughened by the presence of vegetations The portions of the convex aspects of the postero right and postero left segments which overhang the aperture are also slightly coated with vegetations The posterior segment of the pulmonary valve which bounds the aperture above and in front is much thickened and coated with vegetations on both its convex and concave aspects It is clear that during the diastole of the ventricles there must have been a stream of blood impinging on this part of the valve through the two apertures in the aneurysmal dilatation of the aortic segment The portion of the antero right pulmonary flap which is left is normal

The deficiency in the septum is separated from the pars membranacea by a distance of three quarters of an inch on the right side and by a distance of half an inch on the left side, the septum between being altogether fleshy The pars membranacea septi is of small extent, it does not reach so far forward as is usual, and, as is indicated in the sketch (Fig 1), it falls short of the junction of the anterior and postero right segments of the aortic valve

Nature of the Anomaly

At the time I was first seeking an explanation of this particular form of deficiency of the septum of the ventricles I entertained the commonly accepted view that the main stems of the aorta and pulmonary artery were formed from the bulbus arteriosus or bulbus cordis by the division of that tube into two, and that the septum formed in the process of this division extended down into the common ventricle where it was met by the upward growing septum which effects the division of that chamber I therefore saw in the anomaly a failure of fusion between the interventricular and interbulbar septa. I was soon led to modify this view by the study of a paper by Professor Arthur Keith on Malformations of the Bulbus Cordis which appeared in the Quatercentenary Publications of the University of Aberdeen Partly as the result of his own investigations in comparative anatomy and partly from a study of the embryological work of Greil, Keith was able to point out that the fate of the bulbus cordis is different from that mentioned above By far the greater part of the bulbus is developed into the conus

this I cannot go, for though the description is supplemented by plates, these do not supply all the data on which to base a certain opinion

Of the cases recorded by Rokitanski Keith accepted one (Case No 20—that of a boy three years of age), but he rejected the other (Case No 19), as there was clear evidence that the interbulbar septum was complete From his notes on the specimens in the various London museums he was able to give me the following references to cases which appeared to him to conform to the type of that at which I was working One of these, in the Museum of St George's Hospital, was "evidently described by Rolleston in the Transactions of the Pathological Society" The patient was a boy aged 11 years The opening into the right ventricle was three eighths of an inch below the pulmonary valve and "just above the origin of the posterior or fixed, and of the anterior cusps of the tricuspid valve" The second was in Guy's Hospital Museum (No 2309, the patient a female aged 19) The third was in the Museum of the Royal College of Surgeons of England (No 580)

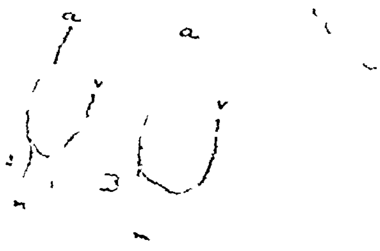
FIG 3

P Posterior pulmonary segment A r Antero-right pulmonary segment A l Antero-left pulmonary segment A, B, P and A r constitute the four *septal segments of Keith* The interrupted line shows the extent to which the aortic root is embraced by the *muscle of the ventricles*

THE CONDITION OF THE ANTERIOR AORTIC SEGMENT

The aneurysmal dilatation of the anterior segment of the aortic valve and its projection into the right ventricle, which I have mentioned, was a striking feature of the specimen This condition of the valve is mentioned by Coupland as having been present in his case also, but the projection was much less and the valve segment was entire To understand the condition one must study the relationship of the root of the aorta to the musculature of the heart and especially to that of the ventricles From a series of dissections I made to [illegible] as to this I found that the root of the aorta is embraced by ventricular muscle on its anterior and lateral aspects, and that this muscular investment extends backwards on the right side as far as the junction of the anterior one third with the posterior two thirds of the right or non coronary cusp, and on the left side as far as the middle of the postero left cusp (Fig 3) The whole of the aorta opposite the anterior cusp is closely embraced by ventricular muscle

FIG 4

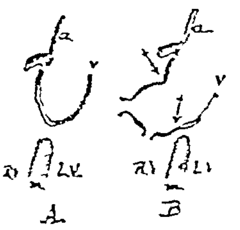


[illegible]

The exact relationship of the ventricular muscle to the aorta and to its valve segments varies in another respect The usual relationship opposite the anterior segment is that shown in the diagram (Fig 4, A) Some ten years ago I put in the anatomical museum a specimen in which the condition was as shown in Fig 4, B The valve segment and the coat of the aorta were apparently completely separated from one another, both could be seen to end rather abruptly except for a thin layer of endarterium which preserved their continuity and through which the muscle of the ventricle could be readily seen

Now in the specimen on which I am commenting there was a complete absence of any support to the aorta and valve corresponding to the greater part of the anterior segment If we conceive the condition resulting from the failure in the complete formation of the bulb septum to be represented by Fig 5, A we can readily understand that the condition shown in Fig 5 B might be brought about by the diastolic aortic pressure There is a slight bulging outwards of the part of the aorta entering into the formation of the *sinus of Valsalva*, but the main part of the projection is formed by the thinned out tissues of the valve segment itself, and this is precisely limited to where the ventricular muscle is wanting—namely, opposite its middle three fifths From an examination of the specimen I should think that during the early phase of diastole of the ventricle the aperture of communication would be closed by the apposition to its concave margin of the anterior aortic segment at the junction of the greatly thinned out portion with the rest of the flap, which in this way would be assisted in supporting the diastolic aortic pressure It will be seen that it is only that part of the segment which is directed to the cavity of the right ventricle which has become stretched and this raises some further considerations

FIG 5



The lettering *a* *v* and *D* as in the *former figure* Shows that the infundibular part of the right ventricle is not cut off from the aortic vestibule of the left ventricle A shows the congenital defect B shows the bulging of the portion *of the segment which faces towards* the right ventricle. The beginning of the bulging is shown by the two arrows.

CONCLUSION

The amount of support which the ventricular muscle gives to the semilunar valves has been discussed by the late Dr G A Gibson and by others Dr Harry Campbell has speculated on the conditions whereby it appears to be the case that the delicate tissue of the aortic valves is able to arteriosus or infundibular part of the right ventricle, a very small portion of limited vertical extent being probably represented by the extreme *upper part of the left ventricle* just at its *opening* into the aorta The aorta and pulmonary artery are not therefore formed from the bulbus cordis at all, but result from division of the common aortic stem In bringing the specimen before the Anatomical Society in 1907 I interpreted the anomaly in the light of these newer views The *aperture became* in my opinion "interbulbar" and was due to an imperfect formation of the septum which divides that part of the heart

In some of his previous writings Keith had described two bands which *are* visible on the posterior wall of the conus of the right ventricle when that cavity is opened from the front These he calls respectively the reptilian and the mammalian band The former descends towards the apex along the ventricular septum and is called the left infundibular or apical band, the latter, which he terms the right infundibular or lateral band, passes outwards on the lateral wall of the right ventricle towards the margo acutus These two bands, as he points out, meet on a raphe which is sometimes quite distinct, and which extends from the commissure of the two septal pulmonary segments above to the pars membranacea septi below This raphe indicates the position of the two ingrowing processes which form the septum of the bulbus cordis It is in the line of this raphe that deficiencies in the bulbar septum are met with and in the specimen I describe it will be seen that the long axis of the aperture coincides with its upper half (Fig 2)

FIG 1

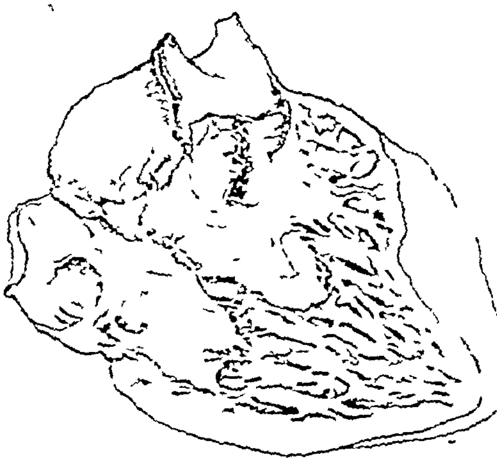
REFERENCES TO SIMILAR CASES

In the article on Congenital Malformations of the Heart by Laurence Humphry in Allbutt's System of Medicine I found references to five cases which appeared to be of the same nature as the specimen I have described Two of these cases were mentioned in Peacock's work published in 1866 (second edition) Rokitansky was credited with two cases and a reference was made to the case recorded by Dr Sidney Coupland in 1879, an undoubted example of the unusual defect I have described The two cases mentioned by Peacock were said to be in the Museum of St Thomas's Hospital, but there was *some ambiguity* in the references he gave Coupland also in commenting on his own specimen mentioned these two cases recorded by Peacock, but I gathered from the context that he had not inspected them himself

As I knew that Professor Keith had about *that time* (1905) been making a very full examination of all the *malformed* hearts in the London museums I *wrote to him on the matter* calling attention *to the ambiguity of Peacock's references,* and asking if he knew the specimen In his reply Professor Keith was very careful to lay down the criteria which should guide us in determining the admission of specimens *to the* class of that described by Coupland which he regarded as essentially the same as that on which I *was working* It was not enough that the aperture as seen from the left side of the heart should be in the same situation, but when inspected from the right side it must open into the infundibular part of the right ventricle, and must not be separated from the pulmonary segments by an area of cardiac tissue which would indicate the completion *of* the septum of the bulb In regard to the reputed cases at the Museum of St Thomas's Hospital he wrote "There is no record of this type of specimen in my notes of the abnormal hearts at St Thomas's Hospital, either Peacock was mistaken, or they have *disappeared*, as they are not now placed with the *specimens on the shelves*" In Peacock's work it is stated that the specimens formed a part of Sir *Astley Cooper's museum*, and that they were described by Dr J R Farre In addition to other abnormalities they are described by Peacock as presenting "a deficiency in the septum interposed between the left and the infundibular portion of the right ventricle immediately *below the* origin of the pulmonary artery I have referred to the original description by Farre The specimens [illegible] described under the heading of [illegible] Pulmonalis Communicating with Both Ventricles [illegible] They are probably both examples of the deficiency further than described by *Coupland and myself*

FIG 2



View from right side [illegible] The [illegible] shown in Fig 1 [illegible] The [illegible] away do not believe, however, that this congenital fold, unless secondarily thickened and contracted by inflammation of the appendix, which is occasionally fused with it from before birth, ever gives rise to the symptoms that have been ascribed to it, or indeed to any symptoms at all. I have made it a rule for nearly two years to look for it where feasible in every exploratory laparotomy, and have found a well marked ileal band in some 10 per cent. of patients of all ages. In no case did I find any distension or hypertrophy of the gut above it as compared with the gut below, nor any definite narrowing of the lumen, nor were the clinical histories or the radiographic findings suggestive of chronic obstruction. Further, in the fibrous form of tuberculous peritonitis one is often struck by the fact that the small intestine can move its fluid contents along without apparent difficulty, in spite of kinks and adhesions that look as though they ought surely to have caused complete obstruction—kinks and adhesions compared with which this congenital anomaly of the lower ileum is insignificant. On all these grounds I feel bound to express my belief that Lane's ileal band, apart from inflammatory changes that may occur in it accidentally, is of little or no importance in the causation of disease, and that the many ingenious operations devised for dealing with it are the outcome of misdirected enthusiasm.

Jackson's pericolic membrane, on the other hand, is a structure which may undoubtedly give rise to symptoms simulating chronic appendicitis, though I hold that it does so less commonly than many writers on the subject would have us suppose. Let me first explain briefly what this interesting peritoneal membrane is. In its fullest development it is a delicate vascular sheet of peritoneum which is occasionally met with, stretching from the parietal peritoneum in the back of the right loin, across the groove or fossa on the outer side of the ascending colon, to fuse with the anterior longitudinal tænia on the cæcum and ascending colon. (See illustration.) It is not an acquired or inflammatory adhesion, as many have maintained, but is of congenital origin, and represents, as I have recently shown,[4] a delay in the process of development or reversion to a primitive type, comparable with such deformities as hare lip or imperforate anus. At an early stage of intra-uterine life, after rotation of the midgut loop, the great omentum extends over the cæcum and proximal colon to the right, and fusing with the anterior longitudinal band or tænia of the colon on the one hand, and the parietal peritoneum of the right flank on the other, becomes the earliest means by which the colon is fixed back into the right loin. Before birth, as a rule, this right process of the omentum almost completely disappears, though a trace of it can always be seen in the living body, but should the proximal colon be unduly mobile from failure of its primitive mesocolon to fuse, the original extent of the omentum may persist as Jackson's pericolic membrane.

In the greater number of these cases the symptoms are due, I believe, not to the pericolic membrane but to the abnormal mobility of the cæcum and ascending colon on which I have a word to say directly. But I have operated on two cases recently in which a much more limited parieto-colic peritoneal band, congenital in origin and a relic of this same structure, had bound down and constricted the ascending colon, giving rise to symptoms which precisely simulated chronic appendicitis.

I come now to the question of mobile cæcum, or, as I prefer to call it, mobile proximal colon, for it is a condition which does not involve the cæcum only. It has long been recognised that there is a not uncommon congenital abnormality of the peritoneum in which the cæcum and ascending colon, instead of being fixed down in the loin, are mounted on a loose mesocolon, continuous more or less with the mesentery of the small intestine; but we are only beginning to realise what grave symptoms may result from this error in development. The mobile proximal colon is the normal arrangement in pronograde mammals such as the cat and dog, but with the evolution of the upright posture fixation of the colon back into the loin by peritoneal fusion became necessary in order to enable the gut to push on its contents against gravity and to resist a tendency to enteroptosis. Our knowledge of the physiology of the colon, though advanced by recent discoveries, is still far from complete, but a study of its comparative anatomy and of the clinical evidence convinces one that these individuals with mobile proximal colons are from birth predisposed to constipation and the multifarious evils resulting from it. I have met with cases of this sort without any pericolic membrane, though the two abnormalities often coexist.

The symptoms of mobile proximal colon often closely resemble those of chronic appendicitis, and actual association of the two conditions is not uncommon, the intestinal stasis and appendicitis being secondary results of the mobility of the colon. Mere removal of the appendix in such cases is not enough, but in addition the proximal colon should be fixed back into the loin by a series of interrupted sutures, and Nature's usual method of fixation of the colon thus imitated. I have seen great relief from severe constipation and right iliac pain result from this operation of colopexy, and believe that it is a far more rational procedure than such mutilating operations as excision of the colon. The preoperative diagnosis of mobile proximal colon is difficult, but the greatest help is obtained by examination of the colon on the fluorescent screen after a bismuth or barium meal.

In addition to the congenital peritoneal adhesions that I have mentioned, inflammatory bands are not rarely met with in this region, both as a result of old standing appendicitis and as a sequel of former tuberculous inflammation. Great and I believe unnecessary confusion has arisen between the congenital and the inflammatory type of peritoneal adhesions, the reason being that until recently the occurrence and significance of the former were not widely recognised. I do not say that it is never difficult to differentiate between them, but broadly it holds true that inflammatory peritoneal bands are tough, fibrous, opaque, and not very vascular, while congenital adhesions are translucent, more yielding, filmy, and vascular. If these distinctions are borne in mind it is usually possible to differentiate between them, though not, of course, before operation.

For lack of time I must pass over the question of ileocæcal growths and massive ileocæcal tuberculosis, though they should properly be considered with this subject, but I must make very brief mention of what is perhaps the commonest cause of an erroneous diagnosis of chronic appendicitis—viz., right chronic tubo-ovarian disease. It is due as a rule to an insidious ascending infection from

support the diastolic pressure of the blood during the whole of a long and active life without giving way, and he concludes that the valves must get support from the part of the ventricular muscle which surrounds their bases remaining in contraction until the pressure in the ventricle has been raised by the entry of blood from the auricle on the relaxation of the general mass of the ventricular musculature The work of Stewart would appear to support this view, and in the Schorstein lecture, which I had the honour to deliver at the London Hospital in 1912, I mentioned a clinical observation which seemed to point in the same direction Those portions of the segment, therefore, which were directed respectively to the right and to the left ventricle would be assisted by the conditions, whatever they may be, which enable the delicate tissues of the pulmonary and aortic semilunar valves to perform a task which, without such help, would be clearly impossible The resources of the left ventricle in this respect are presumably much greater than those of the right, and so it is natural that the portion of the valve which presented to the right ventricle should have been the part to suffer

SOME CONDITIONS THAT SIMULATE CHRONIC APPENDICITIS[1]

BY JOHN MORLEY, CH M VICT, F R C S ENG,
HONORARY SURGEON ANCOATS HOSPITAL, MANCHESTER LECTURER IN CLINICAL ANATOMY MANCHESTER UNIVERSITY

I HAVE chosen as my subject some of the conditions that may simulate chronic appendicitis, because in the latter part of last year a distinguished London physician brought a charge of uncritical and unscientific diagnosis against surgeons in connexion with appendicitis, and crystallised it into the taunt, "the craze for appendicectomy" I realise the very grave measure of justice in that charge Since appendicitis became not only common but fashionable very many appendices have been unnecessarily removed in the absence of any real evidence that they were the cause of symptoms and without any relief to the patients sufferings, and this is a state of affairs that challenges us to approach the diagnosis of appendicitis in a critical attitude of mind

It is in the diagnosis of *chronic* appendicitis that mistakes are most often made, and I propose to limit my remarks to some of the conditions simulating that variety of chronic appendicitis in which there have never been any severe acute attacks—a form of the disease that is characterised by chronic pain and some tenderness in the *right* iliac fossa accompanied as a rule by constipation I do not propose to consider those more distant imitators and associates of chronic appendicitis gastric or duodenal ulcer and gall stones, nor must I stay to discuss lesions of the right kidney and ureter, with which at times chronic appendicitis may be confused I propose only to deal with certain structures in the more immediate neighbourhood of the appendix, and first I have to mention Lane's ileal band and Jackson's pericolic membrane

Lane and his followers hold that the symptoms we are considering, as well as an enormous number of other symptoms, are often due to an intestinal stasis or chronic obstruction, which is caused by an abnormal band of adhesions that we sometimes find attached to the ileum some three inches above the ileocæcal valve Normally the lower ileum rides freely on its mesentery right down to its junction with the cæcum Lane's ileal band, when *present*, is a fold of peritoneum on the left or inferior side of the ileum (see illustration), which tethers the gut down to the parietal peritoneum over the psoas muscle near the pelvic brim It is said by Lane to be acquired as the result of a tendency to enteroptosis and to cause a kink of the ileum and chronic *obstruction* to its contents Others have considered that it is an inflammatory band Both these views of its causation however, have been severely criticised, notably by Gray and Anderson in this country[2] and Flint in America,[3] who drew attention to the frequent occurrence of the ileal band in the full time fœtus and demonstrated its congenital origin I am able from my own embryological and clinical observations to confirm the congenital origin of the band It is the same structure as the genito mesenteric fold of Douglas Reid and is a peritoneal fold drawn down from the left side of the lower part of the mesentery by the testis or ovary in its descent Some trace of it can be made out in almost any fœtus beyond the fifth month though it is only fully developed in a small percentage of cases. I

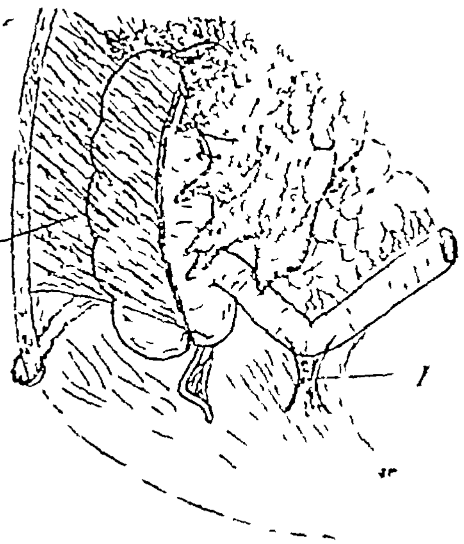

Diagram showing Jackson's pericolic membrane (J) and Lane's ileal band (I) healthy intestine, and it would seem therefore that the gas developed in the peritoneal cavity, which could occur only from the action of some aerogenic organism Many descriptions of such organisms have been published, but only two are generally recognised as producing gases in the tissues apart from putrefactive changes These are the bacillus aerogenes capsulatus of Welch and the bacillus œdematis aerobius of Sanfelice

---

[2] THE LANCET May [illegible] p 130 [illegible]

[3] Johns Hopkins Hospital Bulletin [illegible]

The bacillus aerogenes capsulatus was isolated by Welch in 1891, and described by Welch and Nuttall in 1892[3] A patient from the service of Sir William Osler died from repeated hæmorrhages from an aneurysm which ruptured through the chest wall No gas was observed in the tissues before death, but eight hours later in cool weather there was a general emphysema most marked near the region of the rupture The gas in the veins and tissues ignited with a slight detonation and burned with a pale blue flame An analysis published in 1897 by E K Dunham[4] shows that the gas developed in such a case is composed of hydrogen 64 3 per cent, carbon dioxide 27 8 per cent, and nitrogen, &c, 8 1 per cent In Welch and Nuttall's case it had no distinctive odour and there was no putrefactive odour or green discolouration of the body The bacillus aerogenes capsulatus was found in association with the bubbles of gas and was the only organism that developed under anaerobic conditions When 2½ c c of a pure culture were introduced into the vein of a rabbit no symptom of any kind followed in 5 out of 6 experiments In the sixth the rabbit was seen quite lively 20½ hours after the injection, but half an hour later it was found dead, and after death it became emphysematous This rabbit was pregnant, and two of her fœtuses were macerated and much smaller than the others, having evidently been dead some time When a rabbit was inoculated and killed within two days emphysema always developed after death, and the gas accumulated "with almost startling rapidity" when the rabbit was killed a few minutes after the injection and kept at a temperature between 30° and 35° C Introduced into the vein of a dead rabbit the bacillus caused bubble formation spreading to a limited extent along the vessel

F Fraenkel injected the bacillus into the subcutaneous tissues of mice without effect In rabbits thus treated œdema with necrosis was occasionally produced, followed by recovery In guinea pigs a spreading gangrene with gas formation developed and was followed by death There was no suppuration unless pyogenic organisms were also introduced and in these experiments the production of gas was usually localised in the necrotic area, even after death In 1896 Welch and Flexner recorded 23 cases in which with one exception the bacillus aerogenes capsulatus was identified In no case was gas found in the peritoneal or pleural cavity without hæmorrhagic infarction of the bowel or lung In one case the invasion of the bacillus was limited to two circumscribed areas of intestine The bubbles, from the size of a pea downwards, involved the whole intestinal wall and the bacillus was found in the adjacent tissue, but in no other organ nor in the blood. It was present in the intestine A case related by Graham Steward and Baldwin[5] was quoted in which a woman after a miscarriage became emphysematous all over her body four hours before death

The bacillus œdematis aerobius was first described by Sanfelice In 1901 Corner and Singer[6] recorded a case in which a bacillus was found "identical with that of Sanfelice" In 1904 Dudgeon and Sargent[7] described a case and discussed very fully the bacteriology of the organisms concerned They showed that the bacillus isolated did not cause gas formation when a culture was introduced into the veins of a rabbit which was almost immediately killed. The bacillus was therefore not the bacillus aerogenes capsulatus of Welch. They concluded that their case and that of Corner and Singer were "examples of that small group of cases of emphysematous gangrene which was caused by the bacillus coli" They pointed out, as did Welch, that no one had ever produced gas formation in any animal by injecting this bacillus But when it was introduced into the tissues with the staphylococcus pyogenes aureus (Chauvenez) or with the proteus vulgaris (Muscatello and Gangitano) gas formation had been obtained

The details of the characters of the gas producing bacilli are highly technical, and those interested should study the papers of Dudgeon and Sargent, Welch, and others It seems to me that those of M H Gordon[8] and Theobald Smith[9] are also important These writers have shown that streptococci and staphylococci and the bacillus coli are capable of differentiation into subspecies which breed true It seems to me that these observations offer a satisfactory explanation of the many manifestations which are attributed, for example, to the action of the bacillus coli

The bacilli under consideration are widely distributed in nature They may be found in the intestines of animals, in milk, in surface water, in soil, in cesspools, and in many other surroundings The bacillus aerogenes capsulatus was detected in 69 out of 250 wads of blank cartridges This bacillus seems to develop gas more freely and more rapidly than the bacillus œdematis aerobius, and I think it was the active agent in the case now recorded, but without bacteriological evidence no definite statement can be made The case is, I believe, unique Dr James F W Ross described exactly the same conditions of pneumoperitoneum with contracted intestines, but in his case the condition arose in a woman suffering from puerperal septicæmia with high temperatures The gas was let out 34 days after delivery, but it reaccumulated, and death followed in three days Mr (now Sir Rickman) Godlee published in 1877 three cases of gas and fluid in the unwounded peritoneal cavity, and in one the patient was alive five weeks after the gas and fluid were released This is the only case I the uterus, either gonorrhœal or septic The pain is usually, though not invariably, worse at the menstrual periods, and in some of these cases on palpation in the right iliac fossa there occurs a reflex tonic spasm of the psoas muscle which I have seen mistaken both for an appendicular abscess and for a neoplasm The subject of these ovarian conditions, simple and tuberculous, is far too large, however, to be dealt with adequately now I feel that a too rigid demarcation between surgery and gynæcology has done harm to both, and that surgeons who are constantly operating in the abdomen might well take a far more intelligent interest in the tubes and ovaries than has been customary of recent years

[8] [illegible] on Some Characters by which Various Streptococci and Staphylococci may be Differentiated and Identified

[9] Note on Bacillus Coli Communis and Allied Forms American Journal of the Medical Sciences [illegible] p [illegible]

In cases of chronic pain in the right iliac fossa a careful and thorough physical examination, with an equally careful history, will often enable us to make a fairly confident diagnosis of the underlying condition, but in a large proportion of these cases we must frankly admit that with our present clinical methods a precise preoperative diagnosis is not possible What we can say is that exploration is advisable, since where the pain in this region is persistent and severe there is nearly always an organic cause, capable of relief by well considered surgical means

It is not pleasant to operate without a precise preoperative diagnosis Patients do not like it always, since they are apt to demand omniscience But it is a far more scientific and indeed a more honourable thing to admit our limitations and to explore with an open mind than it is to operate with one's eyes blinded by a positive diagnosis, given where certainty is not truly possible

The lesions which may simulate chronic appendicitis are so many that an adequate incision is imperative There should be no more blind removals of the appendix in these dubious cases through a two inch gridiron incision, but through a sufficiently large incision, usually a vertical one through the right rectus, and preferably under spinal anæsthesia, we should inspect not only the appendix but all the other structures that may possibly have been the cause of the trouble, and we should deal with them according to the actual conditions found, and not according to any preconceived opinion of the thing we ought to find

Manchester

UNIVERSITY OF EDINBURGH ANNUAL REPORT — The annual report for 1914 bears in many places the imprint of the war During the year there were 732 fewer matriculated students than in 1913 The numbers matriculating in the Faculty of Medicine were 1025 or 290 less than in the previous year The marked decrease in the numbers of male undergraduates in the various faculties is of course principally due to the fact that prior to the opening of the autumn session a large body of students actual and prospec

PNEUMOPERITONEUM OF THREE DAYS' DURATION FOLLOWING RESECTION OF A CARCINOMATOUS RECTUM,

EVACUATION OF THE GAS AND OF A PELVIC ABSCESS, RECOVERY, NO RECURRENCE AFTER FIVE YEARS [1]

By JOHN D MALCOLM, F R C S EDIN
SENIOR SURGEON TO THE SAMARITAN FREE HOSPITAL

THE absence of recurrence after five years is satisfactory, but the pneumoperitoneum constitutes the chief interest of the following case

The patient, a stout woman, aged 60, complained of pain and hæmorrhage from the bowel After six months an ulcerated tumour was found in the posterior wall of the rectum but there was no fixation of the part and on Dec 31st, 1909, the rectum was removed in the Samaritan Free Hospital by a combined abdominal and perineal method described by C H Mayo [2] The abdomen was opened the bowel was divided above the new growth and both ends were closed The rectum with as much pelvic fat as possible, was separated and everted through the anus The projected mass was then cut off between the growth and the internal sphincter The remaining part of the rectum was held in its everted position by forceps, and through it the lower end of the mobilised sigmoid flexure was brought down This was opened, and the bowel ends were united by interrupted sutures and replaced in the pelvis The union was considered so accurate that Mayo's recommendation to drain the pelvis through an incision behind the anus was not followed

After the operation the highest temperature was 100° F the bowels acted, and no unfavourable sign was noticed until the sixth morning, when the abdomen was distended The bowels never failed to move when laxative medicine was given and there was no vomiting but the distension rapidly increased and on the ninth day it was very great the abdomen being tense and tympanitic all over and the pelvic floor being pushed down The temperature was 99 2° the pulse rate was increasing but only 118 and of fair volume Respiration was not greatly distressed and the general condition was alarming only because of the increasing distension

The abdomen was reopened and its anterior wall immediately fell with a flop upon the intestines which occupied a very small space A large quantity of gas necessarily escaped and an absence of odour was observed The exposed part of the peritoneal sac contained no fluid and its serous surface was very pale and showed no sign of inflammation The intestines were not adherent except in the pelvis, where all the parts were matted together On separating these many ounces of offensive pus were released The abscess cavity which contained no free gas was drained through the lower end of the incision the remaining part of which healed by first intention and no further accumulation of gas took place After drainage of a secondary collection of pus through an incision in the right groin the abscess healed slowly and otherwise recovery was uninterrupted When the patient left my care the line of anastomosis was fixed by cicatricial tissue, but there was abundant room for the passage of fæces On Dec 22nd 1914 the patient's general health was good and her only [illegible] which necessitated the [illegible] ill effects of any compressing agent effused beneath the window of bone On the other hand, nibbling operations are more difficult and more prolonged, yet there is complete freedom from any fear of inefficient relief of pressure What I suggest, then, is preliminary resection of a flap of soft tissue and bone in the usual way, following this up by "pepper pot" trephining of the flap raised This can be done effectively and quickly with a burr, perforations ⅜ to ½ inch in diameter being drilled at close intervals from the interior of the reflected plaque, right through the osseous tissue, but not including the soft parts The bone flap will then be a sort of retaining cage of a basket-like, fenestrated, or pepper pot texture This should efficiently retain the brain without risk of hernia and yet with satisfactory relief from pressure A diagram of the idea of the operation is given

A THIRD OUTBREAK OF EPIDEMIC POLIOMYELITIS AT WEST KIRBY

By GEORGE JUBB M D GLASG, D P H OXON,

MEDICAL OFFICER OF HEALTH, HARTLEPOOL LATE ACTING MEDICAL OFFICER OF HEALTH, NORTH WEST CHESHIRE COMBINED DISTRICTS.

THE occurrence of cases of poliomyelitis at West Kirby for the third year in succession appears to me to present so many interesting features that I have ventured to put these few notes together, as so far I am not aware that there have been similar occurrences in any other district

The first case in 1914 occurred on August 10th in a house within a quarter of a mile of the solitary case of 1912, and within the same distance of the first case of 1913 and equidistant from many of the other cases of 1913 The father of the first patient is a medical practitioner who attended two of the cases of 1913, and although this may only be a coincidence, yet it opens up a field of speculation and emphasises the importance and necessity of precautionary methods being adopted by all who come in contact with, or have to deal with, acute poliomyelitis The following are the numbers of children attacked in each outbreak 1912, 1 case, 1913, 7 cases[1] and 1914, 4 cases Some brief clinical notes of the cases may be of interest

CASE 1.—A male aged 3 years, West Kirby The illness began on August 10th with violent headache but no sickness He complained also of dryness of the mouth, and his breathing was very laboured and difficult On the 13th twitching of his right arm and leg was noticed, and on the 15th paralysis was definitely established The paralysis of his right arm and leg gradually disappeared and three weeks later the boy was going about practically well The affected muscles however remained flaccid and the right knee jerk absent There were no other children in the house

CASE 2.—A female aged 6 years, Hoylake The illness began on Sept 22nd with headache and sickness On the next day there was complete paralysis of the child's arms and legs and she was unable to lift her head Death occurred two days later (on the 25th). There were two other children in the house, one younger than this case

CASE 3.—A male aged 3 years Hoylake The illness began on Oct 1st with feverishness and vomiting but without headache On the 4th paralysis of the left arm was noticed There were two other children in the house both older than this case

CASE 4.—A male aged 6 years Hoylake The illness began on Oct 2nd with feverishness headache and vomiting On the 6th there was paralysis of both arms and legs, but left arm paralysis was pronounced There was one younger child in the house

Distribution of Cases

Case 1 occurred in West Kirby in the circumstances already mentioned Case 2 occurred in Hoylake, about a mile away from Case 1 It may be mentioned here that Hoylake and West Kirby are practically one town and are model seaside resorts, clean, well drained, and well paved Cases 3 and 4 were also in Hoylake, one on either side of Case 2 and about half a mile away from it No other cases occurred in West Kirby and, as far as is known, no cases developed among visitors after leaving the district No cases were reported from any of the adjoining districts

Possible Sources of Infection

Milk—All the Hoylake cases had a common milk-supply In outbreaks of poliomyelitis it is most unusual to find the milk supply concerned The apparent implication of the milk supply here might, of course, be only another coincidence, but Case 3 was fully a mile away from Case 4, in a well populated district, or rather town, and therefore the milk, with those engaged in its distribution, is bound to fall under suspicion

Dust—The two towns are very clean and free from ordinary dust Sand from the shore is often blown about the towns by the wind, but this is more usual in winter than in summer

Flies—No excessive prevalence of flies was noticed Against the theory of infection by means of flies it may be pointed out that poliomyelitis is increasing, while owing to the diminishing use of horses the chances of infection by biting flies are steadily decreasing

Other insects—In the facts elicited regarding the cases of 1912 and 1913 there appeared to me to be some foundation for suggesting that possibly the infective agent was at times conveyed by means of lice In this outbreak it has not been possible to collect any evidence which would substantiate this theory On the other hand I may say that on several occasions I have been asked if it was possible for sand fleas to convey the infection of poliomyelitis, as most of the children affected had paid recent visits to the shore

Carriers—It is held by many that the disease is spread by carriers, and that the cases are only "unfortunate incidents in a widespread benign infection" (R McLaren) It is quite possible that this is so either directly or indirectly The occurrence of these four cases would appear to support the theory of carriers, and additional support is probably given by the implication of the milk supply

It is worthy of note also that these four cases occurred within a very limited area, and amongst a population of 14,000 and that the disease has taken two years to spread from West Kirby to Hoylake, a distance of only a mile in as already mentioned, a well populated area

In conclusion I may remark that though it was not possible to trace any connexion between Case 1 in West Kirby and Case 2 in Hoylake yet in the recurring outbreaks of three successive years it seems as if one could almost trace a case to case infection I have little doubt that the many puzzles the epidemiology of poliomyelitis apparently presents will much as in the case of malaria be finally solved when the means of distribution of the infective agent is or are clearly established

Hartlepool

[1] THE LANCET, Nov 1, 1913, p 1250

know of except that now related in which an accumulation of gas in the peritoneal cavity has been survived without the closure of a wound through which the gas had passed into that cavity

Wounds associated with emphysema of the surrounding tissues are almost always fatal unless the affected part is promptly amputated Occasionally a cure may be effected by making very free incisions On the other hand, the bacillus aerogenes capsulatus may circulate in the healthy tissues without harm, and the case now related shows that in exceptional circumstances recovery may follow distension of the peritoneum by gas It seems to me that the organism gained access to the tissues during or soon after the operation, but was harmless until the pressure of the abscess diminished the vitality of the adventitious tissue between the pus and the peritoneal cavity sufficiently to allow the organism to develop in that membrane and cause gas formation, whilst some unfavourable condition in the abscess cavity prevented gas production there Conversely the increased vitality of the tissues, brought about by the relief of tension in the abscess and in the abdominal cavity, was sufficient to arrest the aerogenic action of the bacilli

The facts that the bacillus aerogenes capsulatus usually develops only in dead or dying tissue and the invariable association of the bacillus œdematis aerobius with septic organisms have developed a new interest since these notes were written The men of our Expeditionary Force in France are constantly in recently made trenches, where the opportunities are numerous for infection of wounds by anaerobic organisms found in the soil Already a number of cases of emphysema complicating injuries have been recorded, and the bacilli under consideration have been separated from these wounds It is obvious that to prevent the occurrence of this complication, which is almost always an indication of extreme danger, it is necessary to preserve the vitality of the parts in every possible way, and this necessity adds force to the plea made by Sir Watson Cheyne at the Medical Society and by others for an intelligent application of the teachings of Lister to the conditions of the present war Aseptic surgery is impossible when the wounds are made septic as they are inflicted An attempt should therefore be made to sterilise these infected wounds at the earliest possible moment by a vigorous use of antiseptics

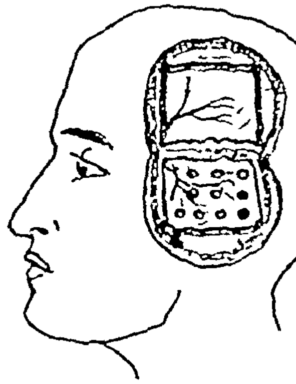
OSTEOPLASTIC RESECTION OF THE SKULL IN DECOMPRESSION OPERATIONS ON THE BRAIN

BY SPENCER MORT M D GLASG, F R C S EDIN
F R S E
MEDICAL SUPERINTENDENT EDMONTON INFIRMARY
UPPER EDMONTON N

Two cases of brain disease with pressure on the cortex which I have at present under treatment have suggested a method in modification of the current procedure in decompression operations and it may be opportune at this time One case shows the disadvantage of removal of a large portion of bone the other case shows the converse difficulty which may arise from replacing a temporarily resected flap of bone

The first patient a male, aged [illegible] years was operated on some months ago by a well known brain surgeon for intracranial pressure, probably due to tumour The bone in the left temporal region has been removed over the silent area, apparently by Cushing's method, and at this date there is a large protrusion of the brain forming a hernia cerebri The other patient a female, aged 60 years was operated on by me 14 days ago There was a fracture of the base of the skull with intradural hæmorrhage, and pressure signs on the left side of the motor area of the cortex

A large flap was made in the soft tissues and four holes were drilled with a Doyen's burr at the angles of a rectangle of bone, measuring 3 inches by 2½ inches With a Gigli's saw the resection was completed and the brain exposed in 15 minutes from the first incision On incising the dura an amount of blood issued and drained away, leaving a pulseless, flat-looking area of cortex The lower anterior drill hole was enlarged with nibbling forceps and utilised as a drain, and the bone with its cover of soft tissue was replaced Relief from pressure was observed for a week, then evidence of irritation recommenced In the next four days there were no less than 450 fits of Jacksonian nature counted, affecting mostly the right side of the face, with conjugate deviation of the eyes to the right and aphasia followed by unconsciousness with Cheyne Stokes respiration due to pressure on the face centres and Broca's lobe Four days after the onset of these seizures—that is, 11 days after operation—the wound was reopened and a quantity of blood clot turned out from the brain surface where it had collected under the bone and caused pressure The whole portion of resected bone was removed from the tissue flap and the skin and muscle and aponeurosis only replaced Immediately and obviously the pressure signs ceased and in the next three days there were but two slight fits observed the breathing and pulse improved and the general condition got better



Diagrammatic sketch to illustrate "pepper pot" trephining for the relief of intracranial pressure

Now this case stands much the same as the first example quoted there is a large bony gap which must either remain to the inconvenience or danger of the patient afterwards, with also the risk of hernia cerebri or else the hiatus must be filled in by bone mosaic, osseous graft or mechanical obturator In similar cases therefore I propose to try the effect of a procedure which I have not seen described before the object of which is to amalgamate the advantages of temporary resection with those of permanent removal of bone

Osteoplastic resection is easy speedy and gives good access, without good drainage to prevent the

King Edward VII Sanatorium show also that it is an unusual occurrence for such patients to relapse after receiving a course of sanatorium treatment and education The treatment, therefore, of cases diagnosed as pulmonary tuberculosis in the absence of tubercle bacilli, though doubtless of value to the individual patients and of interest in other respects, furnishes us with no useful information as to the value of tuberculin All that can be said is that such cases do equally well on sanatorium treatment with tuberculin and on sanatorium treatment alone

The Result of Treatment of 130 Cases in the Sputum of which Tubercle Bacilli were Found

The results were as follows Much improved, 64 6 per cent , improved 17 7 per cent , stationary or worse, 17 7 per cent , lost bacilli, 32 3 per cent These records of general results and for the loss of bacilli are better than any previous records published by the Sanatorium It is essential, however, that it be borne in mind that these figures refer to the treatment of selected cases, for the actual proportion of tuberculin treated cases amounted to but 62 per cent of all the cases treated in the Sanatorium during the period now under review The degree of selection exercised introduces a difficulty in estimating the success of our work, since we have no records of the results in similarly selected cases treated by sanatorium methods alone There is, however, no doubt at all that if the 30 to 40 per cent of less favourable cases were eliminated from our records of results of sanatorium treatment alone the figures would be most materially improved The selection of cases for tuberculin treatment to the exclusion of the less favourable therefore introduces a serious element of fallacy

A Comparison of the Results of Tuberculin treated Patients and Patients treated in the Sanatorium without Tuberculin

The only possible method we have for making a comparison between the results of the tuberculin treated and the non tuberculin treated is to set out the general results obtained for the whole Sanatorium in the pre tuberculin days side by side with similar results obtained since the introduction of tuberculin This gives us a view of the effect upon the general results of the introduction of some 60 per cent of selected cases treated with tuberculin

In the following tables I have set out for purposes of comparison the general results and the effect upon the sputum under the two conditions stated 1 In 764 cases treated in the Sanatorium without tuberculin 2 In the treatment of 172 unselected cases treated in the Sanatorium during 14 months of which cases 64 5 per cent received tuberculin 3 In the treatment of 130 selected cases treated with tuberculin These records refer exclusively to patients with tubercle bacilli in their sputum

TABLE I —COMPARISON OF GENERAL RESULTS

1 *Results of Treatment of 764 Consecutive Unselected Patients (T B + cases) on Sanatorium Methods Alone*

	Arrested or much improved		Improved		Stationary or worse	
Group 1 (1[illegible] cases)	87 9	(161)	6 5 %	(12)	5 [illegible]	(10)
Group 2 (357 cases)	57 4	(2[illegible]5)	20 1	(72)	22 4	(80)
Group 3 ([illegible] cases)	[illegible]	([illegible])	[illegible] 6	(82)	[illegible]2 6	(95)
Total (764 cases)	53 [illegible]	([illegible])	21 7	(16[illegible])	2[illegible] 0	(1[illegible])

2. *Results of Treatment of 172 Consecutive Unselected Patients (T B + cases) during 14 months—March, 1912–May, 1913—of whom 111 or 64 5 per cent , received Tuberculin*

	Arrested or much improved.		Improved		Stationary or worse	
Group 1 (25 cases)	84 0 %	(21)	Nil		16 0 %	(4)
Group 2 (110 cases)	55 4 %	(61)	21 8 %	(24)	22 7 %	(25)
Group 3 (37 cases)	18 9 %	(7)	27 0 %	(10)	54 0 %	(20)
Total (172 cases)	51 7 %	(89)	19 7 %	(34)	28 4 %	(49)

3 *Results of Treatment of 130 (for the most part) Selected (T B + cases) Patients from November, 1911, to May, 1913, treated with Tuberculin*

	Arrested or much improved		Improved.		Stationary or worse	
Group 1 (22 cases)	95 4 %	(21)	Nil.		4 6 %	(1)
Group 2 (81 cases)	70 3 %	(57)	13 5 %	(11)	16 2 %	(13)
Group 3 (27 cases)	22 2 %	(6)	44 4 %	(12)	33 3 %	(9)
Total (130 cases)	64 6 %	(84)	17 7 %	(23)	17 7 %	(23)

TABLE II —COMPARISON OF SPUTUM RESULTS

1. *Results of Treatment of 764 Consecutive Unselected (T B +) Cases on Sanatorium Methods alone*

Lost T B whilst in the Sanatorium —

Group 1	43 1 per cent
Group 2	17 8 ,,
Group 3	6 6 ,,
All cases together	20 5 ,,

2 *Results of Treatment of 172 Consecutive Unselected (T B +) Cases of which 64 5 per cent (111) received Tuberculin*

Lost T B whilst in the Sanatorium —

Group 1	49 6 per cent
Group 2	25 6 ,,
Group 3	8 3
All cases together	25 5 ,,

3 *Results of Treatment of 130 Selected (T B +) Cases Treated with Tuberculin*

Lost T B whilst in the Sanatorium —

Group 1	59 0 per cent
Group 2	33 3
Group 3	7 4 ,
All cases together	32 3 ,,

Admitting the difference in the total number of cases dealt with the records for all cases during the pre tuberculin years, and for a period of 14 months, during which tuberculin was largely used, are strikingly similar They indicate that whilst the use of tuberculin has had no appreciable effect upon the general results as regards the loss of bacilli there has been an appreciable difference 5 per cent more patients having been discharged free from bacilli than in former years It is noticeable too, that the greatest improvement is seen in the group of moderately advanced cases, the figures for loss of bacilli having risen from 17 8 per cent to 25 6 per cent , a significant increase since this group includes the majority of the patients

An Interim Opinion as to the Value of Tuberculin

It is impossible to give anything like a final opinion as to the value of tuberculin on the strength of our present experience Moreover an interim opinion is necessarily limited to the value

ARTERIO VENOUS ANEURYSM OF THE FEMORAL VESSELS, FOLLOWING BULLET WOUND THROUGH THE LEFT THIGH

By W MORLEY WILLIS, F R C S Eng,
SURGEON TO THE GENERAL HOSPITAL, NOTTINGHAM

THIS case is of current interest as it occurred in the present war, and of surgical interest on account of the comparative rarity of the condition

The patient was a private in the Black Watch, and he was wounded at Ypres on Oct 29th, 1914, by a rifle bullet which passed through the upper third of his left thigh, from before backward He was treated for two days at a clearing station, and was then sent into hospital at Boulogne, where he remained for three weeks He says that on the third day after his admission to hospital at Boulogne his wounds were practically healed and he was allowed to get up When he did so he found that on walking about he had a tingling pain in his left foot, and on the second day on which he was up he complained of this to the surgeon who examined him, and found that there was a thrill to be felt in the region of the anterior wound He was put to bed and he remained there until he was sent to England He came straight through to us from Southampton and reached the Nottingham General Hospital on Nov 22nd, 1914

On admission the patient had a pulsating swelling, of about the size of a pigeon's egg, about 4 inches below Poupart s ligament, in the line of the femoral vessels On the upper and inner portion of the swelling was the wound of entrance—healed The swelling was expansile, and there was a well marked bruit to be heard on auscultation A very marked thrill was to be felt, especially in the line of the vessels proximal to the swelling Pressure on the femoral artery caused the pulsation in the swelling to cease These foregoing physical signs left no doubt that a wound of both the artery and the vein had been inflicted, and from the situation it was reasonably probable that the wound in the artery was below the origin of the profunda femoris The patient was kept in bed, and it was observed that the swelling was increasing in size

Operation was performed on Dec 1st The steps of the operation were as follows A long incision in the line of the femoral vessels was made from Poupart s ligament for about 8 inches downwards, and the femoral artery and vein were exposed and demonstrated above the aneurysm, similarly, the artery and vein were exposed below the aneurysm Then around each vessel separately, both above and below the aneurysm, was placed a temporary ligature consisting of small sized rubber tubing In other words, a tourniquet was applied directly to the vessels in the four situations This secured that the further steps of the operation on the injured vessels were quite bloodless The femoral vessels where the bullet had traversed them were firmly adherent to each other and there was scar tissue in the neighbourhood They were carefully dissected from each other and it was found that the artery had a wound in front and behind and that the vein had a wound on its outer side only The situation and relations of the vessels explain this as at the position where the wound occurred the vein is beginning to pass behind the artery Consequently a wound through the artery just caught the outer border of the vein The profunda femoris artery was demonstrated, arising about 1½ inches above the wound in the femoral artery The femoral artery was then ligatured above and below the wound in it, and the wounded portion was cut out The wound in the vein was a longitudinal slit about ¼ inch in length This was repaired by suture with fine silk and intestinal needle, and the continuity of the blood stream restored The temporary ligatures of rubber tubing were then removed from the four points where they had been applied, and the wound was found to be dry, no hæmorrhage taking place from either vein or artery The deep fascia was sutured with catgut and the skin with silkworm gut

The operation was performed under spinal anæsthesia, which was quite perfect The patient made an entirely uneventful recovery, getting up at the expiration of three weeks

Nottingham

THE VALUE OF TUBERCULIN AS AN ADDITION TO SANATORIUM TREATMENT

By NOEL D BARDSWELL, M D Edin,
MEDICAL SUPERINTENDENT KING EDWARD VII SANATORIUM, MIDHURST

I LIMIT myself to the consideration of experience with tuberculin at King Edward VII Sanatorium We have used tuberculin extensively, and as a result of this work we are now enabled to give a partial answer to the question, to what extent, if any, was the benefit to be derived from an average stay of some six months in the Sanatorium increased by the use of tuberculin, as compared with a similar length of treatment in the Sanatorium when no tuberculin was given

Results of Tuberculin Treatment

During the 19 months from October, 1911 to May, 1913, tuberculin was given to 154 patients this number representing 62 per cent of all the patients treated in the Sanatorium during this period Of these 154 patients, 130 (or 84 4 per cent) had tubercle bacilli in their sputum the remaining 24 patients had not They may then be classified as follows 1 Cases in which pulmonary tuberculosis was believed to exist though the presence of tubercle bacilli could not be demonstrated in the sputum, 24 2 Definite cases of pulmonary tuberculosis, tubercle bacilli being present in the sputum (a) Cases of early disease, (Group I) 22, (b) cases of moderately advanced disease, (Group II) 81, and (c) cases of advanced disease (Group III) 27

Results of Treatment in 24 Cases in which Tubercle Bacilli were not Found

These 24 patients all did very well indeed but it is difficult to decide how best to classify them on their discharge To record them as on admission presenting early disease, and on discharge arrested disease would give the encouraging result of something like 100 per cent of complete recoveries Such a record however would be of no value These so called early cases do very well under ordinary sanatorium treatment, it being very unusual for such cases to fail to reach an apparently complete recovery The after history records of successfully treated on ordinary sanatorium lines, plus tuberculin had reactionless courses, and that no one case which was troublesome to immunise on account of reactions was successful, as judged by the loss of bacilli One factor, then, which these successful cases all had in common was a capacity to take increasing doses of tuberculin without reactions, their treatment in consequence presented no difficulty, and in respect of exercise they were able to follow the same treatment as has always been prescribed to favourable cases at the Sanatorium These 40 patients, in short, were all of a very favourable clinical type, they represented 30 per cent of the cases selected as being suitable for tuberculin treatment Although complete recovery, with loss of bacilli, is compatible with a reactionless course of tuberculin when given at the same time as ordinary sanatorium treatment, it is by no means certain that a prolonged reactionless course of treatment will result in any obvious success On the contrary, many of our cases took tuberculin just as well as the 40 cases just considered, over periods, for example, of 30, 40, and 50 weeks and more, but with no apparent benefit That is to say, their progress was identical with the progress made by non tuberculin treated cases which do not lose their bacilli. There is one difference only, in that the tuberculin treated were rendered tolerant to considerable doses of tuberculin

Tuberculin Courses Marked by Reactions

I have been able to extract from our records sufficient evidence to prove conclusively that reactions are a source of danger, fortunately it is not considerable, for our practice has been to discontinue tuberculin so soon as it is evident that it cannot be given without risk In brief, I have observed the occurrence of increased activity of the disease definite extension of the area of disease, the development of acute pleurisy with effusion, and in one case of pneumothorax following upon slight reactions Apart from these more serious effects, I have seen many cases in which favourable progress was retarded by occasional slight reactions or by a slight degree of malaise, unaccompanied by definite febrile disturbance, consequent upon tuberculin inoculations What has impressed me even more forcibly of the grave dangers of reactions are the results of treatment marked by repeated febrile disturbances which continually come under my notice when examining candidates for admission to the Sanatorium During the past 12 months I have seen 14 patients who, beyond all doubt had been seriously injured by inoculations of tuberculin and in many of these, unfortunately, the damage was of an irremediable nature

I would urge most strongly that safety in tuberculin treatment lies in the strict avoidance of reactions, and in my opinion unless this is realised the general use of tuberculin throughout the country will prejudice the prospects of the average consumptive patient

Bandelier and Roepke are of the opinion that if the reacting temperature is not greater than 100·4° F it is unnecessary to decrease the dose Many observers in their practice are bolder than this I entirely disagree with this attitude towards reactions Sahli[1] has much more nearly expressed my views in the following words "One is not justified in provoking febrile reactions and all other manifest toxic actions must be avoided A rise of 4 to 5 tenths of a degree F must be considered as a febrile reaction, if the time of its occurrence clearly shows that it is the result of an injection"

Our own records show that very often reactions to 100° F do no obvious harm, but it is not to the point So long as there is no evidence to prove that they are of any benefit, and considerable evidence to show that the intensity of reactions cannot be controlled, and at any time they may do great harm, there can be no room even for discussion as to what is the correct practice

Tuberculin as an Aid in Diagnosis of Pulmonary Tuberculosis

It is now generally recognised that the production of a local reaction at the seat of inoculation and the raising of the temperature as the result of a tuberculin injection afford no useful information These results merely indicate that infection by tuberculosis has occurred at some time, but do not help us to determine whether or not tuberculous disease exists, and should it exist, whether it is active, quiescent, arrested, or obsolete These facts are not sufficiently recognised On the other hand, the absence of any reaction following a series of diagnostic inoculations excludes the existence of tuberculous disease, and the occurrence of a focal reaction in a suspected organ—for instance, in the case of the lung the development or increase of adventitious sounds—warrants a positive diagnosis Tuberculin for diagnostic purposes, therefore, has a definite though somewhat restricted value

In conclusion, I would express the opinion that it is impossible not to look upon tuberculin sympathetically, for as a means of treatment it at least rests upon a scientific basis Wholesale condemnation and extravagant praise of tuberculin as a means of treatment of pulmonary tuberculosis are alike unwarranted What we now require is more work, accurately observed and carefully recorded, and more of the scientific and critical spirit in our judgments

Midhurst

HUNTERIAN SOCIETY —At the next meeting of this society on Wednesday, Jan 13th at 9 P M, in the Barbers Hall, Monkwell street E C, Mr Donald Armour will deliver the second Hunterian Society's lecture on Surgical Experiences during the Present War All members of the medical profession are invited

LITERARY INTELLIGENCE —As usual, the new issue of the British Pharmacopœia will be accompanied by the publication of several books which are based upon and supplement the information contained in the official work. In this connexion we draw attention to Messrs J and A Churchill's announcements "Materia Medica" fourteenth edition by Dr W Hale White physician to Guy's Hospital "The Book of Prescriptions" tenth edition by Mr E W Lucas a member of the British Pharmacopœia Reference Committee "The Book of Pharmacopœias" by Mr E W Lucas and Mr H B Stevens This is a new book containing about 5000 formulas British and foreign arranged on a comparative system —Mr H K Lewis in announcing for early publication the new (sixteenth) edition of the Extra Pharmacopœia has issued a pamphlet describing the special features of the two volumes into which this work is now divided The new edition has been revised in conformity with the British Pharmacopœia 1914 and a synopsis of the more important changes has been provided —Messrs Smith Elder and Co announce for publication "The Early Diagnosis of Heart Failure and other Papers on the Heart and Circulation" by Dr T Stacey Wilson physician to the General Hospital Birmingham The volume is illustrated by over 100 original diagrams of tuberculin when administered by the method popularised largely by the work of Bandelier and Roepke, which, as the one in most general use, was selected for the first trial We are now using the method recommended by Trudeau and Sahli, amongst others, by which considerably smaller doses are given, thereby securing much greater immunity from the risk of provoking reactions

Our experience as yet has shown that in tuberculin we have not a remedial agent which is to revolutionise either our sanatorium results or our conception of the outlook for the average consumptive Tuberculin is not a cure in the ordinary sense of the term, and no immediate or striking results are to be expected from it, even with the most favourable cases The good effect of tuberculin is at the best exerted almost imperceptibly and over a long period, the slowness of its action being such that it is often difficult to determine as regards patients treated under the most favourable and hygienic conditions how much, if any, of the improvement that takes place is due to its use

As employed at the Sanatorium during the first 18 months of the observations on tuberculin, it appeared to exercise a favourable influence in the treatment of a certain proportion—some 25 to 30 per cent—of the cases admitted to the Sanatorium For a fair number of those patients who can take steadily increasing doses of tuberculin without reactions it is a useful addition to the other means employed in sanatorium practice This favourable influence is to be recognised chiefly in the more rapid disappearance of bacilli As to the kind of case in which we may expect to find tuberculin of assistance, our experience is that it is a patient with a good outlook, who has rapidly responded to general hygienic measures, and who has shown evidence of constitutional vigour and recuperative power Already improving, the addition of tuberculin in the treatment of a good many of such cases seems to expedite the full establishment of convalescence

In a considerable number of cases tuberculin, so far as we can judge from immediate clinical results, has no obvious effect The patient is gradually made tolerant to tuberculin, but this is the only objective indication of its action Further, in a certain proportion of cases tuberculin is more than a negative agent it is positively prejudicial We have received no encouragement in the treatment of febrile cases with tuberculin, and have quite failed to obtain confirmatory evidence of the antipyretic value which some observers have claimed for it Tuberculin cannot be looked upon as a means whereby an unfavourable case can be converted into a favourable one, or as likely to turn the scale in the patient's favour when his progress is hesitating or definitely retrogressive More often than not it will do harm

It follows, then that the administration of tuberculin is quite unsuitable as a routine method of treatment for all cases of pulmonary tuberculosis and that its indiscriminate and careless use on a large scale can only end in disasters

Commentary

It is a matter of opinion how far our experience at the Sanatorium helps us in the solution of the larger issue—namely the therapeutic value of tuberculin It is generally stated that in order to obtain the full advantage the process of immunisation by tuberculin inoculations should extend over a very long period at least a year or more It is for this reason that dispensaries, and sanatoria working in connexion with such institutions, may be expected to attain a greater measure of success than sanatoria working single handed So far as our work at King Edward VII Sanatorium is concerned, there has been no such coöperation, and with but few exceptions the patient's course of tuberculin has terminated with his discharge from the Sanatorium

The question of the continuance of tuberculin treatment by patients after their discharge from the Sanatorium is one of considerable difficulty It is at least very probable that in many cases it would be to the advantage of the patient if his course of tuberculin, already of some four months' duration, could be continued for a very considerable period on his return home At the present time it is impossible in most cases satisfactorily to arrange for this, for, to judge by our experience, the medical profession generally in this country is not yet sufficiently versed in tuberculin administration to warrant their undertaking this treatment with any confidence Further, in my capacity of examiner of candidates for admission to the Sanatorium I continually see most unfortunate results of tuberculin treatment It is true that these bad results are for the most part the outcome, seemingly, of what I should consider to be a faulty method of tuberculin administration At the same time, there is reason to believe that the methods adopted represent a conception of tuberculin treatment which is widely held by the profession at the present time Personally I should like to see the trial of tuberculin upon a large scale, and in respect to the patients at King Edward VII Sanatorium should like to arrange for their tuberculin treatment after their discharge, since the results of such observations could not fail to provide most valuable information I do not think, however, that this extended experiment is justified unless a method of treatment is adopted which is absolutely free of risk to the patient The first essential is to be sure that the treatment will do no harm Herein to my mind lies the crux of the tuberculin problem at the moment

With respect to the Administration of Tuberculin

The administration of tuberculin centres round the question of reactions Is it a serious responsibility to provoke a reaction, or is a reaction nothing worse than a hindrance in the course of immunisation, a transient and harmless episode? Again is it a simple matter to give a full course of inoculations without producing febrile disturbances, or is it a task of considerable difficulty, amounting in many cases to an impossibility? It would seem remarkable that upon such an essential point as the safety of producing a reaction there should be such a divergence of opinion

Our Experience at the Sanatorium

Reactionless course —The evidence is afforded by the records of 40 patients who lost their tubercle bacilli, and who whilst undergoing tuberculin treatment followed the ordinary routine of sanatorium treatment and were fully restored to general health and capacity for work

We naturally turn to the records of our most successfully treated cases to note to what extent their tuberculin courses were reactionless or otherwise, and it is very significant that without exception these cases 0 in number which were thus correct, as syncope rather than asphyxia causes death in cases of large thymus On the other hand, I found nothing that could safely be called status lymphaticus, nor met evidence of that fine capillary bronchitis which Paltauf says is often the cause of death in such cases This case seemed to show a connexion between an enlarged thymus and an undeveloped shrunken condition of both lungs—almost atelectasis

Medical Societies.

ROYAL SOCIETY OF MEDICINE

SECTION FOR THE STUDY OF DISEASE IN CHILDREN

Exhibition of Cases and Specimens

A MEETING of this section was held on Dec 11th, 1914, Mr T H **KELLOCK**, the President, being in the chair

Dr F J **POYNTON** showed a case of ? Aortic Disease, the interest of which lay in the entire absence of any history of heart disease or cause for heart disease except tonsillitis, and in the exact interpretation of the physical signs The patient, a boy aged 5 years, had been sent up to hospital by a school medical officer for heart disease For two years the mother had noticed that the child soon got tired and breathless on exertion There was no history of rheumatism in the child or the parents, also no fever The tonsils were very large and almost meeting The pulse was somewhat irregular, 84, and strikingly small in volume The heart showed no apparent enlargement, and the impulse was not forcible Apex First sound short, and systolic murmur Aortic cartilage Rasping systolic murmur conducted upward and outward There was no thrill over its maximum. This murmur, traced towards the apex got fainter, and then the apical murmur was heard increasing in intensity to the apex It would seem that these were two different systolic murmurs The basal murmur could be heard at the pulmonary base, but was fainter there than in the aortic region

Dr J L **BUNCH** showed a child with Nine Patches of Morphœa The patient, a girl aged 11 years, had developed the first lesion a few weeks previously just below the left iliac crest It had appeared as a dense yellowish white small patch with no suspicion of redness or coloured border The outline was sharp, and the skin over it was distinctly harder than the surrounding healthy skin Eight other similar but smaller patches had since appeared on the chest, back, and shoulders The face was free There was no evidence of peripheral neuritis or ganglionic lesion

Dr **BUNCH** also showed a case of Ichthyosis in a child. The disease had been present since birth and the child was now 8 years old The extensor surfaces were most affected, but the flexor aspects and the face were also involved The epidermis was thickened and pigmented, the surface was covered with a coarse scaliness, and there was pronounced follicular keratosis Subjective symptoms were practically absent

Dr G A **SUTHERLAND** showed a case of Myatonia Congenita with Dilatation of the Colon The patient was a male aged 2 years who had been admitted for an abdominal swelling the abdomen had been noticed to be very large The bowels were usually constipated, recently the motions had been loose scanty, and offensive A large swelling occupied the right side of the abdomen and extended into the iliac region on the left side apparently fæcal The anal orifice was very small and tight X rays showed great dilatation of the colon The abdominal mass was removed by enemata etc and the sphincter ani was forcibly dilated Great improvement as regards the action of the bowels and size of the abdomen resulted The child could sit up but could not stand or pull himself into the erect posture The muscles were small and markedly hypotonic, the joints were very flexible The knee jerks were absent There was no marked rickets There seemed to be some mental backwardness,

Dr **ROBERT HUTCHISON** showed a case of Hypertrophy of the Gums The patient a boy aged 5 years, had had enlarged gums all his life, which now made it impossible for him to shut his mouth properly The gums were greatly hypertrophied, the teeth being almost buried in them. Pus could be squeezed out from around some of the teeth. The boy seemed otherwise in good health

Mr **PHILIP TURNER** showed a case of Pulsating Tumour of the Scalp The patient, a girl aged 18 years, had had for the past nine years a pulsating swelling of the scalp This appeared shortly after a fall in which she struck her head against a concrete floor She was not unconscious after the fall, and there were no symptoms of concussion and no open wound of the scalp The tumour had caused no symptoms, but had increased slightly in size Three or four months ago the skin over the swelling ulcerated and became very septic, but there was no hæmorrhage, as the result of treatment the ulceration soon began to heal There was now a soft pulsating swelling occupying the occipital region and extending nearly to the vertex An X ray examination showed no opening in the bone, though the surface appeared irregular and grooved

Dr J D **ROLLESTON** showed a specimen of Cerebral Embolism in Diphtheria from a girl, aged 8 years, admitted to hospital on Oct 24th with severe faucial and nasal diphtheria on the third day of the disease Large doses of antitoxin were given, and the throat became clean on the 28th, but the same day the heart, hitherto normal, showed some dilatation and weakness of the first sound The voice became nasal on the 30th At 11 15 A M on Nov 7th she retched, the respirations became rapid, the colour cyanosed, and a convulsive movement of the right arm and loss of consciousness ensued Double ankle clonus and double extensor response were obtained Both abdominal reflexes were lost, but the corneal reflex, though absent on the right, was active on the left side A cardiogram showed premature ventricular contractions The pulse was 115 On Nov 8th the pulse was 160, and during short paroxysms rose to 220 The specimen showed embolism of the basilar artery, of the superior cerebellar arteries, and to a greater or less extent of all the arteries entering into the formation of the circle of Willis—viz, the posterior cerebral, posterior communicating, internal carotid, anterior cerebral, and middle cerebral arteries The lesions were much more marked on the right than on the left side An ante-mortem clot was found in the left ventricle and a small infarct in the left kidney

Dr E B **GUNSON** showed a specimen of Pericarditis in Scarlet Fever The patient, a girl aged 15 years, was admitted to hospital suffering from scarlet fever on the thirtieth day of disease She had never had rheumatic fever, but had had occasional "growing pains" On admission the temperature was subnormal The patient was pale The pulse was regular, with a rate of about 100 per minute The heart was not enlarged In the mitral area there was a short, sharp first sound, followed by a loud rough systolic murmur, conducted to the axilla Endocarditis was diagnosed, and the patient was kept in bed The temperature remained subnormal until the thirty fifth day, when it rose to 101° F. Slight pyrexia persisted On the thirty-eighth day the pulse became irregular owing to each alternate beat being due to a premature contraction The arrhythmia persisted for two days only On the fortieth day pericarditis developed accompanied by arthritis Death occurred on the forty fourth day Post mortem the parietal and visceral layers of the pericardium were completely but loosely adherent by recent fibrinous exudate When the layers were separated and the exudate was detached numerous small subepicardial hæmorrhages were disclosed The heart muscle was pale The cusps of the mitral and tricuspid valves were thickened, and there were some recent vegetations on the mitral valve The left auricle presented a patch of mural endocarditis There were a few small patches of atheroma at the commencement of the aorta Microscopically the left auricle showed thickening of the endocardium, with areas of commencing necrosis, myocarditis, organising pericardial exudate containing a number of irregularly dilated capillaries The right auricular muscle presented a similar appearance, the endocardium was healthy The left ventricle showed acute myocarditis of mild degree

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

NOTE ON A CASE OF SUPERNUMERARY TOES

BY WALTER FALLA, M R C S ENG, L R C P LOND

A FEMALE patient, aged 22, recently consulted me for an interesting and unusual deformity of her right foot, which caused her considerable inconvenience in walking owing to the overlapping of some of the toes The left foot was normal, but the right one was considerably broader and was provided with eight fully developed toes, three of which were on one side of the big toe and four on the other, and each one articulated with a separate metatarsal bone Owing to the rarity of this malformation I had the foot photographed Fig 1 shows the foot in its natural position, with the toes overlapping each other, and Fig 2 shows the toes spread out I amputated at the metatarsal joints the two outer toes and the one next to the big toe on the left, the result being that the patient can now walk without the slightest discomfort There is no family history of any such deformity, although the patient has several brothers and sisters

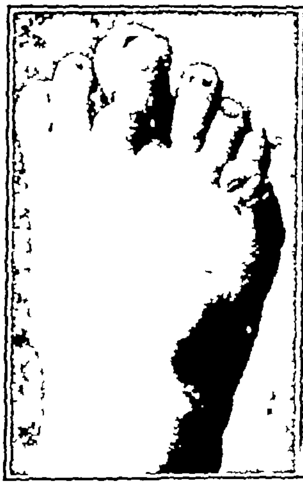

FIG 2

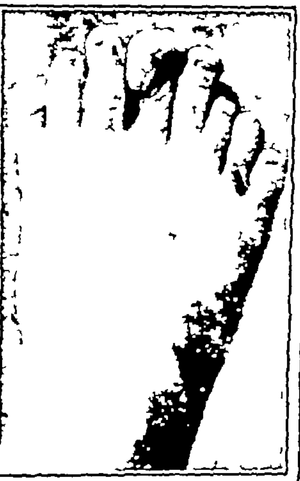

Jersey

NOTE ON A CASE OF GOUNDOU

BY R SEHEULT, M D EDIN,

RESIDENT SURGEON COLONIAL HOSPITAL, TRINIDAD B W I

THIS singular and obscure condition, which is characterised by the formation of hard, smooth, symmetrical tumours at the side of the nose similar to exostoses occurred in a little negro girl who came under my notice in February, 1913 She was born in Tobago in 1902, and arrived in Trinidad about eight years ago with her mother who gave the following history In 1910 she noticed a small swelling on each side of the child's nose, the swellings were hard and painless and increased slowly in size until about two years ago when they appeared to become stationary the child complained occasionally of slight headache and of a feeling of obstruction in the nostrils, there was no nasal discharge No history of yaws or syphilis could be elicited The mother had had nine children, all healthy When the child came under my observation the swellings were fairly well marked, they were hard, smooth, and dome shaped, standing off the surface about ½ inch the skin overlying the growths was natural and freely movable Examination of the nares and mouth revealed nothing abnormal, and the presence of these swellings did not appear to cause any discomfort to the child It may be of interest to note here that both tibiæ were distinctly thickened and that the mother stated there was a case of yaws in her house when the child was two years of age

This is the only case of goundou, or what appears to me to be goundou, I have met with during the 20 years I have been connected with the hospitals of the colony, and I can find no previous record of the occurrence of this affection in the island The condition is reported to be fairly common in West Africa, but its etiology remains in obscurity Some affirm that the morbid process begins during or soon after an attack of yaws, whilst others maintain that it is started by the larvæ of some insect which find their way into the nostrils, others, again, are of opinion that the condition is *sui generis* Dr Albert J Chalmers has published in THE LANCET a report of six cases of this disease under the name of "Henpuye"[1] Dr Henry Strachan[2] has reported an instance of this strange disease in a Jamaica negro child, and suggests that it may be an example of atavism referable to some tribal peculiarity of the original West African stock In my case I was unable to elicit any history of the larval invasion of the nostrils, nor was there any clear evidence or manifestation of yaws—a disease however, which was extremely common a few years ago and is still prevalent in Tobago, where the child was born and lived during three years

A CASE OF ENLARGED THYMUS AND ATELECTASIS

BY J C MCWALTER, M D DUBL, LL D N U I,

EXAMINER IN MEDICAL JURISPRUDENCE AND DEPUTY GOVERNOR OF THE APOTHECARIES' HALL, IRELAND

THE charge of "overlying" made against mothers whose infants are found dead in bed and the sudden deaths which unexpectedly occur during operative procedure have given rise to a comfortable theory of the status lymphaticus which supersedes or supplements the older theory of "thymic asthma" as a cause of otherwise inexplicable death

In the present state of our knowledge it seems a duty to record the particulars of any case where an affection of the thymus gland may have been the cause of death A short time since the infant of a woman whom I had been attending was found dead in the bed The police suspected overlying or negligence and an inquest was held At the post mortem examination the body was found to be well nourished weighing 12½ lb, the age being 3 months There was uncurdled milk still present in the stomach and all the organs appeared to be healthy but the thymus gland seemed enlarged—being bigger than the heart, whilst both lungs were of a somewhat purplish and collapsed atelectasoid condition

I attributed the death to asphyxia probably aggravated by the enlarged state of the thymus gland It is doubtful if this conclusion was really necessarily depressing statement every zoologist will subscribe.

---

[1] THE LANCET, Jan [illegible]

[2] Ed Med Jour, Jan [illegible]

It is most interesting, when revising our knowledge of the general aspect of Lamarck's great contribution to biological theory, to find, as Mr. Elliot points out, that nowhere in the treatise is there a hint that its author had got even the slightest inkling of "Natural Selection." It is occasionally, and even with a desire to depreciate, suggested that Darwin obtained much light from reading the "Philosophie Zoologique." As to theory, that is quite plain; as to fact, it must be borne in mind that Lamarck, writing at that epoch when palæontology was in its infancy, embryology hardly known, and the whole of histology a secret for the future, could hardly be regarded as having accumulated a store of facts for the future delver. Apart from the general purpose of his book, Lamarck dealt necessarily or parenthetically with a vast number of interesting minor points. It was he who first divided the animal world into vertebrates and invertebrates, a division which has lasted for long. It has not, of course, escaped Mr. Elliot that this classificatory generalisation, though "for long time regarded as final," is not now any longer possible, nor has he failed to note that Aristotle's division into "blood-forming" and "bloodless" animals is virtually the division of Lamarck, though based upon a different and incorrect structural feature. One of the most singular doctrines incidentally held by Lamarck was that there are virtually no extinct forms; that all creatures evolved continue to live and progress. It is the more singular since it seems to contradict the great writer's fundamental doctrines. For if the environment can profoundly change, it would seem a corollary that it could produce the final change of all and extinguish. But it must be again recalled that palæontology had advanced but a little way in Lamarck's time, while the exploration of the land, and especially of the sea, was only just beginning. Hence the strong possibility, again and again proved to be partially true, that forms hitherto supposed to be missing would eventually be discovered.

We commend the reading of Lamarck's "Zoological Philosophy" to all biologists, for the author's name is in many mouths while his actual teaching appears to be forgotten. And the wise reader will season his reading with the valuable hints given by Mr. Elliot in his admirable and comprehensive introductory remarks.

---

of assimilable or non-assimilable sugar in the normal organism does not produce diabetes or any of the symptoms or complications of diabetes which have been attributed to hyperglycæmia. His experiments with injections of dextrose produced chiefly negative results that tended to show that the obesity sometimes associated with diabetes was not due to hyperglycæmia. He has not noted anything like a specific toxic effect of sugar, and has found that the only field of usefulness for dextrose injections was to exert a valuable nutritive and strengthening effect in states of weakness.

The author then deals with the diuretic action of sugar and discusses fully the amboceptor hypothesis. A chapter is devoted to the oat cure, including von Noorden's original views on the matter, and the author touches upon the widely different tendencies of different foods to produce glycosuria without regard to the carbohydrate content of these foods. As a result of the experimental production of operative diabetes on various animals he has reached the conclusion that the normal pancreas is necessary for normal carbohydrate metabolism, in view of one of its internal functions, and he holds that the complications of diabetes, at any rate, such as defective wound healing and diminished resistance to infection, albuminuria, &c., as far as he observed in diabetic dogs, are not due to the sugar content of the blood or urine. Diabetes insipidus, he suggests, ought to be classed with the disorders of internal secretion.

A most important chapter is on the nervous system in glycosuria, in which the author puts forth the hypothesis that human diabetes is in most cases a functional disease of the nervous system, and holds that the average diabetic patient may have a pancreas which does its normal work if relieved of abnormal influences which interfere with it, though he holds that diabetes is solely and invariably a disease of the pancreas. Such a hypothesis, he thinks, introduces the hope of therapeutic mastery over the disease. Under the heading of "Miscellaneous Therapy" he deals with many lines of treatment.

In Chapter XIV. Dr. Allen discusses the polyglandular doctrine, and though recognising a certain degree of interaction and interdependence between the different organs of the body, he nevertheless disagrees with the hypothesis that diabetes consists in a loss of balance between antagonistic glands of internal secretion. In a chapter on anatomy he discusses fully the

Dr E G L GOFFE showed a specimen of Pericarditis in Scarlet Fever from a girl aged 9 years She had been admitted to hospital on Oct 9th with scarlet fever There was a previous history of rheumatism On admission the symptoms of scarlet fever were well marked and there were choreiform movements of the face, right arm, and right leg On Oct 26th she developed a pericardial rub at the base and a presystolic and systolic apical bruit Death took place on Nov 2nd The specimen showed the parietal and visceral layers of the pericardium completely covered with recent lymph, small vegetations in the mitral and aortic valves, and some hypertrophy of the myocardium

Dr GOFFE also showed a specimen of Perforation of the Arch of the Aorta by a Safety Pin Impacted in the Œsophagus from an infant, aged 10 months who had been admitted to the North Eastern Hospital on Feb 18th, 1912 certified to be suffering from scarlet fever As the diagnosis of scarlet fever was not confirmed on admission the child was sent to an isolation ward It was seen again late the same evening when the nurse reported that it was fretful and had vomited a little milk after each feed At 12 30 P M next day, Feb 19th, the child vomited after a feed of milk and brought up a quantity of blood and died The œsophagus larynx, and trachea with the arch of the aorta and the large vessels arising from it were shown with a brass safety pin *in situ* as found post mortem The œsophagus had been opened at the back The pin was open with the open end downwards Viewing the œsophagus from behind, the catch half of the pin was seen in the œsophagus, the other half, having passed through the œsophagus point downwards and forwards was not seen The pin portion passed to the left of the trachea on a level with its bifurcation The œsophagus was perforated on its anterior surface about 2 inches from its upper extremity, the pin half having passed completely through the wall of the œsophagus was in a cavity about ¼ inch in diameter between the gullet and the aorta The walls of the cavity were thickened Viewing the specimen from the front there was seen a perforation in the wall of the aorta with the point of the pin just appearing through the hole in the interior of the artery The aorta was perforated about ¼ inch below the origin of the left subclavian Death was due to hæmorrhage from the aorta owing to ulceration set up in its walls by the presence of the pin in the tissues between the aorta and gullet The bleeding was into the œsophagus The stomach was full of blood There was little blood in the upper part of the small intestines No blood was found in the large intestines The heart and blood vessels were practically empty, and all the tissues were pale and bloodless

Dr ERIC PRITCHARD and Dr C VIOLET TURNER showed a specimen of Liver Abscess from an infant aged 5 weeks It had been healthy at birth and jaundiced at 4 days for nearly a fortnight Its abdomen had always been prominent but became much more distended five days before admission to hospital On admission the liver was enlarged down to the umbilicus and there was œdema of the abdominal walls back legs scrotum and penis Death occurred 24 hours after admission The necropsy showed an abscess of the size of an orange in the right lobe of the liver No other suppurative focus was found The pus from the abscess grew bacillus coli and a Gram negative diplococcus A culture from the heart's blood grew bacillus coli

Zoological Philosophy An Exposition with re[illegible] to the Natural History of Animals

By J B LAMARCK Translated with an Introduct[illegible] HUGH ELLIOT London Macmillan and Co, [illegible] 1914 Pp 410 Price 15s net

THE "Philosophie Zoologique" of Jean Baptiste Pierre Antoine de Monet de Lamarck (to give the author's full name, which will not be at all familiar to most of us) is one of the great classics of zoology largely quoted, but mainly quoted at second hand and seldom read There is such an immense gulf between the zoology of to day and that of the beginning of the last century that even the most learned and encyclopædic author, if writing on the results of investigations, hardly finds it necessary to deal with views framed in compulsory ignorance of the quite fundamental data of modern biology It is however, by no means uninstructive to realise what a great deal of truth was arrived at by the acute French philosopher which has been perhaps rediscovered in modern times For example in comparing living and lifeless bodies, Lamarck writes that no inorganic body possesses individuality —a view which reminds us of the more accurate dictum of the physiologist Verworn, who dwells upon a similarly expressed and important character of living beings, these are, he says, characterised by indivisibility, or rather undividedness an expression which embodies the same idea in perhaps clearer terms

In the main, therefore the republication in an English dress of the famous philosophical work of Lamarck is a matter of historical interest To those readers who are not fully informed of the chief theories and data of biology Mr Hugh Elliot's introduction will be of very great service This editor has not only fully grasped the general purport of Lamarck's thoughts, but is able to elucidate from the modern point of view his statements of fact Without this introduction the text of Lamarck would be in many places obscure save to the very well instructed reader Mr Elliot places his pen at once upon a common misinterpretation of the "Philosophie Zoologique" by pointing out that that philosophy had two leading contentions To most persons Lamarck's insistence upon the inheritance of acquired characters and the gradual heaping up through this of at first infinitesimal variations which lead under the influence of the environment to the production of new species, represents his philosophical position in the matter of evolution But this would be an incomplete and thus misleading idea For Lamarck prefaced this axiom of his belief by the assertion that an innate power of development tending to proceed in a straight line is conferred upon all animals It is the divergencies from this straight line that are due to the environment as [illegible] already stated To pursue any criticism of Lamarck's position is obviously impossible in [illegible] review nor would it be of great [illegible] [illegible] rather [illegible] with Foster that the [illegible] life of any theory is no more than [illegible] In the last published reflection upon the [illegible] problems of evolution Professor [illegible] [illegible] addressing the British Association [illegible] years of patient work [illegible] still [illegible] we can hope [illegible] problem [illegible] always agreeable, sometimes pathetic Of the 71 boys, 6, after drifting about for three years, found their way into occupations where they learned skilled work or its equivalent, 44 boys were found to be doing unskilled work, and likely to continue in the ranks of unskilled labour, 21 boys were also doing unskilled work, and were so markedly deficient in mental, moral, or physical capacity—sometimes in all three—as to make it exceedingly probable that they would be rejected for regular employment

The stories of the boys' lives are given in many cases, it is often pitiful reading, the *lacrimæ rerum* are there. Sometimes there are redeeming features, as in the boy whose father had committed suicide through drink, and whose mother earns a pittance by mounting brass knobs at a factory The boy does odd jobs and is apparently destined to sink into the ranks of unskilled employment, but during the coal strike, "in order to get some coal for his mother, he went down to the canal, dived into the icy water, and fetched up lumps of coal from the bottom piece by piece" The influence of the picture palace in the lives of town children is very great, all boys go to the cinema, generally twice a week Mr Freeman considers it as unquestionably "the greatest formative influence at the present time in the life of the average working boy' There is not much of a directly vicious nature in this influence, he thinks—and this accords with all we have heard—the boy is on the whole innocently amused, but it initiates him "prematurely into the adult point of view It merely multiplies and intensifies the boy's stock of common place ideas without enlarging or ennobling them" On the whole this is a more favourable opinion in regard to these shows than we should have expected The music hall performance is condemned for boys

The remedies proposed for the existing evils in boy life and labour are absolute prohibition of wage earning, accompanied by whole time education, up to 15, reduction of hours of juvenile labour between 15 and 18 to a maximum of (say) 30 per week, compulsory continued education, to be insisted on by the State the details being settled by the local authority The reduction in hours would 'fall most severely on those firms and occupations that make an illegitimate and parasitic use of boy labour , but everyone will agree with Mr Freeman in his opinion that "no firm has a right to use a boy for one season only of the year, or for a few years of his life, and then cast him adrift at the expense of the community"

Bedside Hæmatology an Introduction to the Clinical Study of the So called Blood Diseases and of Allied Disorders

By GORDON R WARD M D Lond. London and Philadelphia W B Saunders Company 1914 Pp 394 Price 15s net

From the title of this book we should rather have expected a short manual dealing with the methods of examination of the blood which can be used at the bedside, without the provision of an organised laboratory It is actually designed on different lines

After an introductory chapter on classification and one on the general physiology of the blood forming organs about nine pages are devoted to methods of examination of the blood The succeeding chapters deal in turn with the affections of blood forming tissue, such as chloroma and lymphadenoma, with the various anæmias, with disturbances of the blood pigments, such as hæmochromatosis, hæmoglobinæmia, and so forth, with the varieties of leucocytosis, with chlorosis, hæmorrhagic disorders, and leukanæmia. Three pages are devoted to the study of the blood in surgical diagnosis, and 11 to methods of treatment, including transfusion, X rays, arsenic, and iron. The last chapter contains an alphabetical list of diseases with a brief statement of the conditions of the blood respectively found in them Parasitic diseases of the blood are specially omitted. There are a good many illustrations, showing both clinical appearances and microscopical specimens Two coloured plates of cyanotic patients are of very indifferent merit

The volume does not seem to make any very novel contribution to the subject with which it deals

Surgery, its Principles and Practice For Students and Practitioners

By ASTLEY PASTON COOPER ASHURST, A B, M D F A.C S, Instructor in Surgery in the University of Pennsylvania, &c With 7 coloured plates and 1032 illustrations in the text, mostly original. London Henry Kimpton 1914 Pp 1141. Price 28s net

THIS is a very successful attempt to provide for the student and practitioner a useful and trustworthy treatise on surgery It is not too lengthy, and yet it contains practically all that the student should know for most examinations within limitations which are admitted by the author The author has purposely omitted all reference to the surgery of the eye, the ear, the nose, and the throat In the preface it is stated that they are "naturally" omitted, though we must confess that we cannot see why these omissions should be "natural," even if convenient On the whole, we cannot help thinking that it would have been better from the point of view of the student to have included these sections of surgery, for the special text books on these subjects are generally too lengthy to be easily digested by the student

We have above used the word successful in speaking of this work, and we are justified in doing so, for the book is clearly written and the author speaks with that amount of dogmatism which is best suited for the instruction of students It is evidently the product of a capable teacher The illustrations form a very noteworthy feature of the work, and they are nearly all absolutely original and have been carefully chosen The coloured plates are especially worthy of mention

A Text book of Medical Diagnosis

By J M ANDERS and L. N BOSTON Second edition, revised With 500 illustrations London and Philadelphia: W B Saunders Company 1914 Pp 1248 Price 25s net

THE first edition of Anders's and Boston's massive text book of medical diagnosis was designed to "present, consistently with a single volume textbook, the full modern resources of the art and science of medicine as related to medical diagnostics The second edition, now before us, has taken two years to prepare, and every effort has been made to bring it fully up to date

The general arrangement is excellent A brief introductory section is followed by some 135 pages on diseases of the respiratory system Next the diseases of the circulatory, digestive, and nervous disorder, with impaired function of the islands of Langerhans which leads to a deficiency of pancreatic amboceptor, and this results in glycosuria and other symptoms" He accentuates the fact that a functional disorder must be curable, and if such be established by other observers the existing hopelessness regarding this disease should be removed

We have been able only briefly to touch upon the scope of this work, and the numerous experiments carried out for so many years well deserve most careful study But we are convinced that many good and original ideas are here incorporated, and the entire work will serve to advance the study of this disease There is an appendix of methods, together with protocols of the many experiments, and an extensive bibliography containing nearly 2000 references

---

Essentials of Physiology

By F A BAINBRIDGE, M D Cantab , D Sc , Professor of Physiology, University of Durham , and J ACWORTH MENZIES, M D Edin , Lecturer on Physiology, University of Durham College of Medicine With 134 illustrations, some coloured London Longmans, Green, and Co 1914 Pp 434 Price 10s 6d net

THIS publication makes the fourth of the series of "Essentials" issued by the same publishers In the text there is no indication as to the respective parts contributed by the two authors As far as possible histological details and descriptions of chemical and experimental methods are excluded Only the facts and principles of physiology are considered, and in the main great accuracy is shown, as well as judgment in selecting what to notice But in a future edition we look to see improvements

After three pages of introductory matter and about ten on the chemistry of the body, the reader passes on to muscle, nerve fibres, the central nervous system, and the organs of sense In the tracing showing a "simple muscle twitch' the latent period is obviously much too long It is hardly correct to say that when a muscle passes into rigor mortis it loses its extensibility nor is it quite accurate to state that "the nerve fibres form the medium by which the various structures of the body are brought into communication with the central nervous system' What about chemical means? In the short statement as to the chief chemical constituents of nerve fibres, water seems to find no place In describing the conduction of a "disturbance' in a nerve fibre propagated in both directions it might be well to state what kind of a nerve should be used when the galvanometric method is employed About 70 pages are given to the nervous system, 50 to the organs of sense, and about 20 to blood, and nearly 70 to the vascular mechanism We are glad to see an account of the arrangement and uses of the 'heart lung preparation of Knowlton and Starling Just over 40 pages suffice for the respiratory system The account of the gases of the blood is concise as is that of the regulation of the respiratory movements There are several useful illustrations Some of Barcroft's recent work on the respiratory function of the blood is incorporated

The digestive system is dealt with in 50 pages the subject being introduced by a short account of enzymes The treatment follows the usual lines Metabolism comes next and is set forth in 26 pages while about five pages are given to animal heat About nine pages are given to food and diet We are glad to see that Chittenden's estimate of the protein daily intake is regarded as much too low, so that the actual amount of protein required—about 110 to 120 grammes—is much higher than that taken in his experiments Vitamines are referred to, and the disease produced in fowls by feeding them with polished rice is also noted, but "polyneuritis' as such is not mentioned at least we failed to find it The introduction of an illustration of this condition in the fowl or pigeon and its cure by yeast would have been useful It is stated that "gelatine cannot replace other proteins in a dietary" About 20 pages suffice for the urinary system, and of these seven are given to the urine The authors conclude that the glomeruli simply filter off from the blood a fluid identical in composition with blood plasma, excluding protein, while the tubules, besides secreting certain urinary constituents, exert a selective power of absorption whereby certain substances, such as sodium chloride, can be retained when required A short account is given of the ductless glands Seven pages suffice for reproduction A considerable number of the illustrations are taken from Starling's "Principles of Physiology" and other text books In all cases the sources are duly acknowledged

To us it seems that these "Essentials" are good so far as they go, but being "essentials" the reader must not look for many details They are intended to meet the requirements of the medical student preparing for a "pass examination" There are very varying standards for a "pass,' and for some boards at least it would be well for the candidate to supplement the "essentials" with additional matter from larger text books

---

Boy Life and Labour the Manufacture of Inefficiency

By ARNOLD FREEMAN M A With Preface by M E SADLER, LL D C B London P S King and Co 1914 Pp 252. Price 3s 6d net

AN extremely interesting inquiry has been made into the conditions of juvenile employment in Birmingham by Mr Arnold Freeman, who has recently published his results Mr Freeman conducted his investigations at the request of the Birmingham city education committee of the Birmingham city council His special purpose was to ascertain the causes of deterioration in character and in earning capacity in many boys who fail to pass at once into the higher grades of labour but escape the special temptations of street trading and casual employment He selected from the files of the Labour Exchange every boy of 16 to 17 years of age who had been in four or more situations since leaving school This selection excluded boys of special merit or with favourable opportunities on the one hand and on the other, the nomad or casual, or street arab Of 134 boys so traced, it was possible to follow up in detail the careers of 71 An outline of these boys lives is given and of the influences that are shaping their future

As Dr Sadler the Vice Chancellor of the University of Leeds says in his introduction Mr Freeman following Mr Charles Booth and Mr Seebohm Rowntree has gone straight to life He discloses the actual experiences of a number of boys during their critical years of development The result is a volume of very great interest It is not an impression, but a series of photographs not and details a number of cases We do not, however, think that the authors have sufficiently impressed upon their readers the vital importance of extreme care in the administration of the drug if mishaps are to be avoided Some very striking illustrations are given of syphilitic lesions before and after the injection of salvarsan Curiously we have not been able to find in the book any reference to neosalvarsan

First Stage Hygiene By ROBERT A LYSTER, M D, Ch B Birm, B Sc Lond, D.P H Twelfth impression (sixth edition), revised and enlarged London W B Clive, University Tutorial Press, Limited 1914 Pp 288 Price 2s 6d net —Judging from the issue of a sixth edition the author s plan of taking into consideration the various parts of physiology as essential introductions to certain sections of hygiene has succeeded In addition, he has preserved a logical sequence of both physiological and hygienic facts, which develops the subject in the most intelligible way As an example we may mention that after describing the phenomenon of respiration he proceeds with a chapter on ventilation Similarly the chapter on foods precedes that on the digestive system, and so on through the book This seems to us to be an eminently sound way of teaching hygienic principles, and particularly in the "first stage"

Prothèse Restauratrice Bucco faciale et Traitement des Fractures des Maxillaires By Dr P MARTINIER and Dr G LEMERLE With 172 illustrations Paris Baillière et Fils 1915 Pp 360 Price 3 francs—This handy volume contains a clear account of the various appliances which the dental practitioner is at times called upon to make or have made and to adopt Not only is there an account of the mechanical appliances for treating cleft palate and restoring lost portions of the maxillæ, but details are given of the manufacture of an artificial larynx and the more common methods of replacing a lost nose There is a full account of the different splints for treating fractures of the jaws some of the methods suggested for dealing with extensive injuries of the maxilla being extremely ingenious The illustrations are clear We can cordially recommend the book to the notice of those interested in the subject

MISCELLANEOUS VOLUMES

As might have been expected the war has had its effect in delaying the appearance of some of the books of reference which usually are published at the close of the year The following reached us too late to include in our last issue for

issue contains many articles dealing with topics of timely and paramount interest Some 30 pages are devoted to the war, aviation receives a large amount of attention, the Home Rule question is dealt with, and, indeed, on whatever subject information is desired the searcher is sure to find valuable assistance —— *Whitaker's Almanack, 1915*, by John Whitaker, F S A (London Whitaker Pp 690 Price 2s 6d) is such an old friend that praise of its utility would be almost an impertinence All the well-known features of this publication are maintained in the new edition and among fresh matter there are articles on topics connected with or having a bearing upon, the war —— *Whitaker's Peerage, Baronetage, Knightage, and Companionage, 1915* (same publishers Pp 867 Price 5s net), fulfils all the requirements of an indispensable work for the reference shelf All the promotions and appointments due immediately to the war have been recorded up to as late a date as the exigencies of "going to press" would allow —— *Howe's Classified Directory to the Metropolitan Charities for 1915* (London Longmans Green, and Co Pp 173 Price 1s) gives full information of more than 1000 metropolitan charitable institutions grouped according to classes An appendix contains a list of provincial charities It is a useful guide for the benevolent and we ourselves are grateful for the information which it conveys

JOURNALS AND MAGAZINES

The Philippine Journal of Tropical Medicine, Vol IX, Section B, No 3—No fewer than ten original articles appear in this number of the journal, the first being by Dr Fernando Calderon who gives some data concerning the Medical Geography of the Philippine Islands This observer finds that the three preponderating diseases in this region are pulmonary tuberculosis, malaria and dysentery, after these come beri beri intestinal parasites gastro enteritis, bronchitis, and broncho-pneumonia. Dr Otto Schöbl supplies a paper, with illustrations, on the Etiology of Trichomycosis palmellina a pathological condition of the hair associated with a bacterial infection, found in the Philippines A contribution to the Bacteriology of Leprosy with illustrative microphotographs is made by Dr John A Johnston in the form of a preliminary note, in which the author says that at the present stage of his investigation he is quite convinced that the bacillus lepræ is but the acid fast stage of a markedly pleomorphic streptothrix Dr David G Willets writes on Intestinal Helminthiasis in the Philippine Islands as indicated by examinations of prisoners on admission to the Bilibid prison at Manila, the same author contributes also another short article on Widal reactions among healthy adult Filipinos Dr W A Musgrave and Dr A G Sison supply a joint paper on Bacillary Dysentery and its Treatment this being the most prevalent form of the disease in Manila Experiments on the Cultivation of Rinderpest Virus in the manner described by Baldrey are related by Dr William H Boynton, of the Veterinary Division of the Manila Bureau of Agriculture and the same writer also contributes an article with illustrative plates on Kidney Worm Infestation of Swine in the Philippines with special reference to the pathological changes caused by the parasite Stephanurus dentatus which urinary systems, acute infectious diseases, animal parasitic diseases, and constitutional diseases are discussed, Dr T H Weisenburg at the end of the book contributes 180 pages dealing with diseases of the nervous system Under the heading of each disorder *considered in these groups of* diseases, the arrangement of the information given and the deductions to be drawn from it are equally skilful Admirable use is made of large type headings and subheadings, in such a way that the reader's attention is directed to the salient points without delay The text itself is trustworthy, speaking generally Full weight is given to the laboratory diagnosis of disease as distinguished from its diagnosis by clinical *methods* and observations, and illustrative cases are quoted where this has been thought advisable An interesting example of a mode of infection in pulmonary tuberculosis, oddly enough set down under the heading "Heredity," may be quoted "Seven resident physicians in a hospital in Philadelphia developed pulmonary tuberculosis within the course of two years, and investigations made to ascertain the *source of such infection* disclosed the fact that the coloured cook who prepared the food for the resident staff was suffering from a chronic form of pulmonary tuberculosis, both his saliva and his nasal secretion showing the presence of tubercle bacilli"

The book is well printed, but the authors are often unfortunate in their spelling of classical words —e g, "bacillus smegmae" (p 975) for "smegmatis", "Parongonimus Westermanni" (p 79) for "Paragonimus westermani", "streptothoracosis (p 79) probably for streptotrichosis, "streptothricosis" (p 923) for "streptotrichosis On p 3 they introduce a new "*portmanteau* word, to adopt Lewis Carroll's term—namely, "corollating" apparently a combination of "correlating and "corollary The index is excellent, and so are many of the illustrations *it is questionable*, however, whether any good purpose is served by the many photographs of nude *women* employed to illuminate points of pathological and surface anatomy and scattered throughout the text The book may be recommended to students and practitioners of medicine

---

Indispensable Orthopædics

By F CALOT Translated from the sixth French edition by A H ROBINSON, M D Durh, M R C S Eng, and LOUIS NICOLL With 1259 illustrations and 8 plates London Baillière, Tindall and Cox 1914 Pp 1175 Price 21s net

IT is not quite clear to whom this volume is "indispensable" It consists simply of an account of the methods of the author and is *in no sense* a text book of orthopædics either for the student or for the practitioner It is translated without any attempt to employ English idiom is diffuse and by no means easy to read As a scientific treatise its value is impaired by absence of any consideration of the detailed pathology of the conditions treated and of any recognition of varieties of disease For example there seems to be no differentiation in the author's mind between cases of tuberculous [illegible] of the knee in which there are localised foci [illegible] in the bone [illegible] cases in which the disease is purely [illegible] Dr Calot the descriptions of the technique of work with plaster of [illegible] celluloid are full and good and much attention is paid to methods of aspiration of abscesses It is for these details that the work is useful in England But the view of treatment taken by the author is very circumscribed, personal methods being repeated again and again, and other methods *being mentioned mainly to be criticised There is a good deal of praise of the results of treatment at* Berck in general

The book is well printed and illustrated its chief merit, as already stated, lies in the descriptions of *the author's methods*

LIBRARY TABLE

First Book of Physiology and Hygiene By GERTRUDE D CATHCART, M B, B Sc Glasg, D P H Camb With 65 *illustrations* London Macmillan and Co, Limited 1914 Pp 158 Price 1s 6d net —This is an admirable little text book for the non professional student, written with great clarity and *freedom from unnecessary technicalities*, and yet with noteworthy accuracy The principles of hygiene and their special application to the *common matters of everyday life* are dealt with *in the physiology* of the part to which they pertain, there are, however, special chapters on the hygiene of the skin, hair, and teeth, body heat and clothing, muscular exercise, gymnastic rest and sleep, and micro organisms The author has well succeeded in her attempt to give to the manifold facts of physiology and hygiene a more coherent form by grouping them round certain central ideas which make an appeal to the imagination *Each chapter is followed by a selection* of questions set at the Oxford and Cambridge Local Examinations We can heartily commend this book

Quantitative Analysis by Electrolysis By ALEXANDER CLASSEN, with the coöperation of H CLOEREN Translated *from* the thoroughly revised fifth German edition by WILLIAM T HALL New York John Wiley and Sons London Chapman and Hall Pp 303 Price 10s 6d net —*The introduction of electrolytic* methods of analysis was due to the authors of this volume and they have proved to be very valuable to a large body of analytical chemists but chiefly to those engaged in *metallurgical* work or in the analysis of metallic salts The method is not confined, however, to such well known and easily deposited metals as copper, lead silver bismuth *mercury* and zinc for the list now includes the metals of the alkaline earths the alkalies and even the determination of nitric acid in nitrates Of the greatest assistance in analysis is the electrolytic method applied to the separation of the metals when more than one is present in the solution The description of this application of the electrolytic method forms a most interesting portion of the work and more space is devoted to it than any other The book is a valuable addition to the library of the analyst in general practice

The Salvarsan Treatment of Syphilis in Private Practice with an account of the Modern Methods of Diagnosis By GEORGE S STOPFORD-TAYLOR, M D Durh, M R C S Eng, and ROBERT W MACKENNA, M A, M D [illegible] Physicians to the Liverpool Skin Hospital London William Heinemann 191[illegible] Pp [illegible] Price 5s net —The value of salvarsan is almost universally acknowledged [illegible] This little work gives an account of the method of [illegible] pharmacist will be expected to dispense the new tincture, and it would remove any doubt the dispenser might have if the prescriber were to write "tinct strophanth. 1914"

Tincture of opium —This has been increased in strength by about 33 per cent. The tincture of the 1898 Pharmacopœia was standardised to contain 0 75 per cent of morphine, but the new tincture contains 1 per cent and is approximately the same strength as the tincture of the International Agreement In prescribing it would be advisable to indicate that the 1914 tincture is intended Incidentally it may be noted that as the new tincture contains 1 per cent of morphine it is within Part I of the Schedule of Poisons, and may only be sold by retail to persons known or introduced to the seller and on condition that an entry of the transaction is made in the poison book. The old laudanum was in Part II of the Schedule of Poisons Compound tincture of camphor (paregoric) contains one-tenth more morphine than was contained in the corresponding preparation of the British Pharmacopœia, 1898 Liniment of opium has been increased in the strength of its morphine content

Tincture of aconite —This is about twice as strong as the corresponding preparation of the 1898 Pharmacopœia, and approximately the same strength as the tincture of aconite of the International Agreement Prescribers should indicate the date of the Pharmacopœia.

Vinegar of squill and vinegar of urginea —Both these are approximately twice as strong as the old preparations

Spirit of juniper —This is twice as strong as the old preparation

Syrup of chloral —This is nearly 10 per cent stronger than the old preparation, 1 fluid drachm contains 10 9 grains of chloral hydrate

Syrup of codeine phosphate —This has been increased in strength by 9 per cent, 1 fluid drachm contains 0 27 grain of codeine phosphate.

Calomel ointment —This is twice the strength of the corresponding preparation of 1898

Tincture of nux vomica —This is about half as strong as the old tincture, 1 fluid drachm contains about one sixteenth of a grain of strychnine

Tincture of colchicum —This is one half the strength of the old tincture

Tincture of digitalis —This is four fifths the strength of the old tincture

Ammoniated tincture of opium —This contains approximately one-tenth less morphine than that contained in the corresponding preparation of the 1898 Pharmacopœia

Tincture of belladonna —This contains seven tenths of the proportion of alkaloids contained in the 1898 tincture it is standardised to contain 0 035 per cent of total alkaloid

Tincture of picrorhiza —This is twice the strength of the corresponding preparation of the Indian and Colonial Addendum 1900

Belladonna plaster —This is one half the strength of the old preparation

Hypodermic injection of cocaine —This is one-half the strength of the old preparation, 110 minims contain 5 grains of cocaine hydrochloride

Hypodermic injection of morphine —This is one half the strength of the old preparation, 110 minims contain 2 5 grains of morphine tartrate

Phosphorus pill —This contains 1 per cent of phosphorus and is one half the strength of the old preparation

Phenol lozenges —These are one half the strength of the old, each lozenge contains approximately half a grain of carbolic acid

Phenol ointment —This has been reduced in strength by 25 per cent it contains 3 per cent of carbolic acid

Ammoniated mercury ointment —This is approximately one-half the strength of the old preparation

Compound mercury ointment —This is approximately three fifths the strength of the old preparation

Mercury ointment —This is approximately three fifths the strength of the corresponding preparation of the 1898 Pharmacopœia

Liniment of mercury —This contains approximately three fifths of the proportion of mercury contained in the old preparation

Solution of mercuric chloride —This has been reduced in strength from 1 in 875 to 1 in 1000

Solution of potash —This is nearly 20 per cent weaker

Syrup of ferrous iodide —This is approximately two-thirds the strength of the corresponding preparation of 1898, one fluid drachm contains 3 75 grains of ferrous iodide

Tablets of nitroglycerine —These have been reduced in strength, each tablet contains approximately 1/130th grain of the trinitroglycerine of commerce.

Dilute nitric, phosphoric, and sulphuric acids have all been decreased in strength.

OTHER POINTS

The above represent most of the noteworthy changes in the strengths of preparations Many of them have been made in order that the compounds may comply with the recommendations of the International Conference respecting the unification of the formulæ for potent drugs and preparations in the several national pharmacopœias Alterations, for the most part slight, have been made in the composition of various articles For instance, the saffron has been omitted from compound decoction of aloes; salicylic acid has been omitted from solution of atropine sulphate, the syrup in compound mixture of iron has been replaced by glucose and a small quantity of powdered acacia added, in compound tincture of cardamoms the raisins have been replaced by glycerine, from compound tincture of cinchona the saffron has been omitted, in compound tincture of senna the raisins have been replaced by glycerine

For the most part the changes in nomenclature are not likely to give rise to many difficulties It is interesting to note, however, that liquor iodi fortis (strong solution of iodine) has been replaced by tinctura iodi fortis (strong tincture of iodine) Tinctura iodi is replaced by tinctura iodi mitis (weak tincture of iodine) The strong tincture of iodine of the new Pharmacopœia contains approximately the same proportion of iodine as the strong solution of the old, and the weak tincture of iodine contains the same proportion of iodine as the tincture of iodine of the 1898 Pharmacopœia. It is important that prescribers should note this change in nomenclature, and indicate definitely whether they require the strong or the weak tincture to be dispensed "Tinctura iodi" by itself might leave the dispenser in doubt as to which tincture was intended. Practically all the drugs that have been added are already familiar to medical men, and the more important of these drugs were detailed in the article which appeared in THE LANCET of Oct 10th, 1914 p 907

THE PUBLIC HEALTH OF DUBLIN

THE annual report for 1913 on the state of public health in Dublin has recently been issued by the superintendent medical officer of health, Sir Charles Cameron So much attention has been directed to the sanitary condition of Dublin within the past 12 months that the present volume may find more readers than most of the series

The population of Dublin in the middle of 1913 was estimated to be 308 187 and the density was 39 persons per acre The actual density in the inhabited area is really much greater, as the city boundaries include large stretches of pastoral land Some of the information given is not easy to understand, and contradictory statements occur For instance, we are told (p 18) that the "number of persons residing in single room tenements" is 21,133 It appears from a table on the next page that this is the number of single room tenements, and the number of persons, as stated in the report of the Departmental Committee on Housing Conditions in Dublin[1] is 73,973 Again, in discussing the deaths from typhoid fever, it is said that the number in 1913—viz. 33—is the smallest on record except in 1910, when 32 occurred A table on the next page shows that in 1912 there were only 30 deaths Again, a statement concerning the death rate from infectious diseases (p 35) is copied without correction from the previous report. Slovenliness of this kind makes it difficult to arrive at the facts

The birth rate for the year was 31 per 1000 of the population, whereas in the suburbs it was only 17 per 1000 The birth rate in the city shows little or no tendency to decrease The death rate for the year was 21 3 per 1000, and in the suburbs it was 16 1 per 1000 Of the deaths in the Dublin that fluid The result of this increased osmotic pressure is to "press the blood out of the pulp through the tubules of the dentine up to the enamel The plasm spreads itself out under the enamel and presses it outwardly The paper is interesting if not convincing There are no demonstrations of facts, and some of the author's statements do not tally with unchallenged clinical observations —The January issue of this journal contains the first instalment of a paper by Mr J F Colyer on the Injuries of the Jaws and Teeth in Animals The paper is founded on a museum demonstration given at the Royal College of Surgeons last October, and refers to the specimens in that collection The author describes cases of fracture of the maxilla and the mandible, as well as fractures involving the zygomatic arch Amongst the latter a description is given of the skull of a bear in which there was a definite bending of the cranium from the unequal balance of muscular action Cases of complete dislocation of the teeth and several examples of injury to unerupted teeth are fully described Sir Arbuthnot Lane contributes a paper on the Mechanics of some of the Bones of the Face He discusses the subject from a general point of view, refers to the relationship of deformed arches to adenoids and points out the value of early operation in cases of cleft palate Mr F J Pearce has a practical paper on the Treatment and Filling of Root Canals and there is a good review of dental surgery in 1914

---

[1] THE LANCET, [illegible] pp 623, 624

The British Dental Journal —*In this journal for Dec 15th* 1914, Hubert Humphrey recounts experiments he has carried out on the action of the essential oils on gutta percha He finds that eucalyptus dissolves gutta percha, that cinnamon and cajuput have no action, and that oil of cloves leads to an increase in size, accompanied by hardness He considers that oil of cloves is therefore the best oil to use in conjunction with gutta percha for filling the root canals of teeth J C Storey contributes an article on Efficiency in Work and C Edgar Thomas has a paper on Some Toothache Charms, in which, amongst other interesting details, he states that there is a church at Bonn which possesses a tooth of St Appollonius the patron saint of dentistry, and that this relic is exhibited *in a glass case on* that saint's particular day devotees kissing the relic as a precaution against toothache

Bulletin of the International Office of Public Hygiene Paris 195 Boulevard Saint Germain —The monthly bulletin of the International Office of Public Hygiene we are glad to note continues to appear in spite of the war In the list of the governments published in every issue as participating *in the work of* international *organisation* for public health purposes the names of Germany and Austria Hungary do not appear On the other hand Turkey has joined Of the powers of the entente the following are included Belgium Great Britain France Russia and Serbia *Our ally Japan is missing*, but *Japan* is a long way off and her coöperation is certain to be obtained later in effect, in spirit it has been most faithfully given Some distant countries have joined, such as Chili and Peru and of course Australia, Canada and the United States The *Bulletin* gives frequently *news from the countries* that do not participate in the international organisation for which it is the official organ Thus a few months ago Professor Neisser's researches on the contamination of those who nurse typhoid patients were described These statistics published in Berlin set forth that on an average out of 100 persons engaged in nursing typhoid patients three contract the disease He also affirms that 1 per cent of the men and 7 per cent of the women nurses without showing any symptom of disease become chronic typhoid carriers In the German Empire in 1913 according to Professor Neisser there were at least 70 such germ carriers and he urges that there should be a compulsory examination of all who nurse typhoid patients The reprinting of the Decree dated Paris Oct 1st 1913 and signed by the President of the Republic on the handling of dirty linen in laundries is wise for here another subject of first importance in times alike of peace and war is dealt with Only large steam laundries are under notice the absurdities of the little private laundries situated in the dirty houses of dirty slums are not regarded as laundry operations The guiding principle is the absolute separation and disinfection by the process of washing of all the dirty linen before it enters the part of the premises devoted to ironing sorting and storing the clean linen Then we have a circular issued by the French Minister of the Interior, Public Health Department, dated Sept 25th, 1914, concerning sanitary *measures* applicable to places inhabited by troops The first part deals with the purification and storage of drinking water, and the second part the cleansing and disinfecting of the premises The use of the eau de Javel is much recommended a fact our English medical services on the Continent should not neglect for it is so popular can be obtained everywhere and does not awaken hostile prejudice like carbolic acid Further we have the text of a circular issued by the Swiss Federal Government to all the Cantonal governments dated Sept 29th 1914 on measures that are to be taken to prevent the spread of typhoid fever At that date there was no epidemic but apprehension was created by the increase of sporadic cases Therefore practitioners are called upon to be more prompt and careful to notify all cases and to take all the precautions necessary when they merely notice suspicious symptoms and before the presence of the disease is fully confirmed These are only a few instances showing the practical bearing of the information the *Bulletin* contains, and it is always encouraging to note how sanitary measures are adopted by such a large number of different nations

THE NEW PHARMACOPŒIA

THE publication of a new British Pharmacopœia is an event of great importance to the medical profession, not so much by reason of the fact that it discards a certain number of more or less *obsolete* drugs and gives official sanction to others that were not included in the previous edition but mainly because it alters the strengths of various commonly prescribed galenical preparations without changing their names The omissions and additions are, of course of interest for various reasons, not the least important of which is that they represent the progress that has been made in therapeutic science and so far as the additions are concerned set up standards for drugs that had hitherto been unofficial But from the immediate practical point of view a new Pharmacopœia always needs to be most carefully examined for changes in the potency of its tinctures extracts, and other compounds As Sir Dyce Duckworth recently observed in commenting upon the omission of musk and sarsaparilla from the new Pharmacopœia "that will not prevent their employment"[1] while as regards the newly recognised drugs, most of these have been in common use for many years, and will involve little change in medical practice A general outline of the *new* Pharmacopœia was given in THE LANCET *of Oct 10th*, 1914 (pp 901 and 937) and we now *deal* in greater detail with points with which it is essential that medical practitioners should become familiar without delay Notice of publication dated Dec. 31st 1914 appeared in the *London Gazette* of Jan 1st, 1915 and according to law the new standards and formulæ came into force immediately Therefore all prescriptions written from the beginning of this year should be dispensed according to the new standards unless the prescriber expressly states otherwise The actual number of important changes in strengths is not large but some of the alterations are drastic and unless special care is taken in prescribing the preparations in question undesirable results may follow

CHANGES IN POTENCY.

The following are the most noteworthy cases in which the potency of preparations has been changed

Tincture of Strophanthus.—This is four times the strength of the tincture of the 1898 Pharmacopœia the official dose has been reduced to one third The alteration in strength has given rise to much criticism the object of the change presumably being to bring the tincture approximately to the strength laid down in the International Agreement The tincture of the Pharmacopœia of 1885 was double the strength of the 1898 tincture and therefore half the strength of the 1914 tincture It would be advisable for practitioners—for a few months at any rate—in prescribing tincture of strophanthus to indicate clearly whether they mean the tincture of 1898 or that of 1914 If [illegible] of strophanthus [illegible] any qualification [illegible]

THE LANCET.

LONDON SATURDAY JANUARY 9, 1915

The British Pharmacopœia, 1914

THE receipt of an advance copy of the British Pharmacopœia enabled us[1] to give some indication of the chief changes which would come into force when the new volume was authoritatively published The actual date of appearance was, however, left uncertain at the time, and now that the publication has been gazetted medical men and pharmacists must all be grateful for the consideration shown by the General Medical Council in keeping back the volume to the latest possible moment There can be no doubt that the introduction of a new pharmacopœia is always associated with some inconvenience, both to the medical profession, who have to become acquainted with changes which may affect prescribing, and to pharmacists, who are obliged to revise their stock in accordance with the new standard These difficulties are greatly increased while the nation is at war Apart from a natural disinclination to be troubled with a fresh source of anxiety, there is, in many instances, the impossibility of obtaining from abroad many of the drugs necessitated by the directions of the new Pharmacopœia The declaration of war found the General Medical Council fully prepared to deal sympathetically with these difficulties In the absence of the President on the continent, Dr NESTOR TIRARD, the medical editor, represented to the Executive Committee the grave inconvenience the public services and manufacturers would incur through the early publication of the new Pharmacopœia, with the result that the statutory notice of publication in the official gazettes was postponed from Oct 9th to Dec 31st Thus three months have been allowed to elapse between the exhibition of advance copies and the time of publication during which period many reviews in technical journals have enabled manufacturers and others to make ready Our advertisement columns show that this time has been adequate for the production of new editions of text books, it is to be feared, however, that in some directions manufacturers may still find difficulty in meeting the requirements of the new standard, but no serious trouble should arise so long as care is shown in indicating when articles conforming to the Pharmacopœia of 1893 are necessarily employed in place of those of 1914

On comparing the published volume with the advance copy it is found that the editors have made full use of the opportunity afforded by the delay in publication, they have introduced numerous minor alterations, especially in footnotes, which add to the uniformity and utility of the book as a work of reference, they have also been able to profit by criticisms which have drawn attention to certain elusive misprints which had escaped observation While minor blemishes have thus been removed, the main facts persist, essentially as in the advance copy Reviewing the criticisms which have hitherto been published, exception has been taken to some of the synonyms, to the introduction of the metric system and to a list of abbreviated Latin names of official drugs and preparations which has been adopted in the index The synonym which appears to have caused the greatest uneasiness, if not dismay, is the retention of the term "laudanum" as the equivalent of tinctura opii To conform with recent foreign pharmacopœias this tincture has been made about one third stronger than before, thus bringing the sale to the public under restrictions which may be irksome to the retail vendor Numerous letters of protest have been published on this subject in the trade journals, but if the recorded sales are to be believed it would certainly appear to be high time to introduce some check upon the supply of laudanum to the public Apart from trade considerations, however, the alteration in the strength of tincture of opium is one which should early be recognised by all who prescribe or dispense this preparation. The introduction of the metric system has already caused some unrest amongst medical practitioners, who fear it is too late for them to learn to prescribe in a new fashion. This modest distrust is quite unnecessary, since in the preface of the Pharmacopœia nothing can be more clearly stated than that the use of the metric system is primarily intended for pharmaceutical and analytical computations, and that practitioners are at liberty to employ either the metric or imperial system for prescribing purposes It is necessary, however, to call attention to the fact that the relation between metric and imperial doses is given in approximate equivalents It is perfectly clear from the wording of the preface that at the next revision the imperial system will probably be omitted and it therefore becomes important that the rising generation of medical men should become familiar with the use of the metric system in prescribing as well as in physiological, pathological, and other laboratory work The adoption of the metric system is not only more scientific, but it is also more in accord with the custom adopted in other pharmacopœias

In our leading article on the advance copy reference was made to the above mentioned list of abbreviations, which has furnished many critics with scope for levity It should be noticed that these abbreviations are not authoritatively enjoined, they do not form part of the monographs which constitute the Pharmacopœia. The idea of some authoritative guidance is very welcome, registration area 42 6 per cent occurred in the various workhouses hospitals, asylums and prisons

---

[1] THE LANCET, [illegible]

The death rate from the principal infective diseases, 2·4 per 1000, was the same as in the previous year No death from small pox has occurred in Dublin since 1904 There were 11 deaths from typhus fever, the average for the previous ten years being 3 The number of deaths due to diarrhœal diseases and enteritis of children under 2 years of age was 470 being more than double that of the previous year The high incidence of these diseases is in part due to the long, hot summer of 1913 and in part to the distress arising out of the labour disturbances in the city The infantile death rate for the year was 154 per 1000 births, as against 140 in the previous year

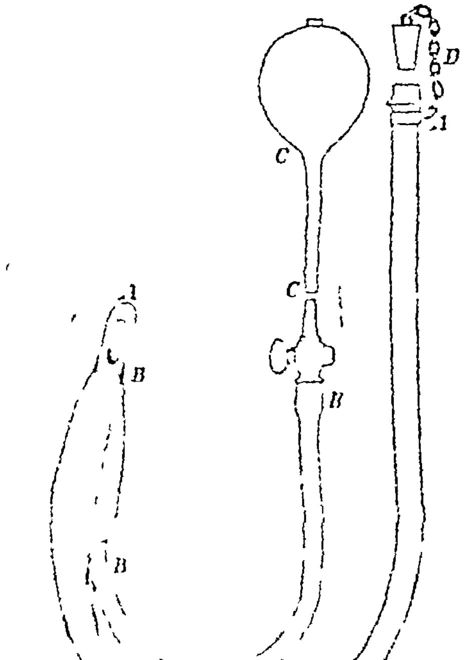
The deaths due to tuberculosis numbered 1132 of which 839 were from phthisis The total is less by 157 than the average for the previous five years The tuberculosis dispensary in Charles street came into the possession of the corporation at the end of 1912 In 1913 1559 patients were treated the number of attendances at the dispensary being 10 533 54 per cent of the patients were males A little more than half were insured under the National Health Insurance Act

Sir Charles Cameron publishes as an appendix his reply to the report of the *Departmental Committee on Housing Conditions in Dublin* Notice of it has already been taken in THE LANCET

New Inventions.

AN OBTURATING CATHETER

I WAS consulted about some bronchial affection in the case of a man 83 years of age, who as the result of an unsuccessful attempt at a suprapubic prostatectomy bore an opening from the skin into the bladder, from which the continual dribble of urine made him most uncomfortable



which at its end has a stop cock and a detachable bulb C C for inflation After passing it through a small infla[illegible] and introducing it into the bladder it is fastened to the body by means of a waist band in the manner of a truss The air bag is then inflated to the extent required completely to occlude the opening At the other end of [illegible] which is attached to it by a small chain and can be easily withdrawn for micturition The patient however for whom the instrument was intended was so intolerant of the slightest accumulation of urine in his bladder that he preferred to connect it with an ordinary urinal when he went out in his bath chair or driving

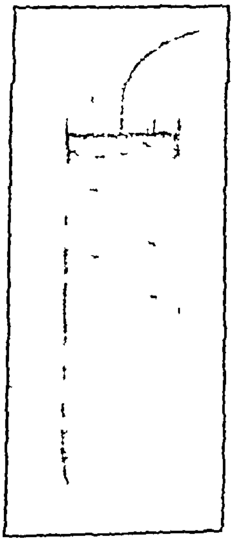
INTRATRACHEAL ETHER ANÆSTHESIA

THE method of giving open ether with a Schimmelbusch mask has been attacked on the score of pulmonary complications which are alleged to follow All who use this method are familiar with the frozen dew which collects on the outside of the mask, and it is difficult to believe that *breathing air at such a low* temperature does not in a certain number of cases prejudice the after results To obviate this I have devised an apparatus for giving hot ether vapour which I have used most *satisfactorily both as regards* immediate anæsthesia and after effects The apparatus (see Fig) consists of a thick glass test tube fitted with a rubber cork, through which pass a glass outlet tube and two terminal connexion The terminals are connected to a U shaped spiral resistance wire which reaches to the bottom of the test-tube The current can be used direct from an ordinary cautery plug The passage of the current through the wire boils the ether, which passes off through the outlet tube to the patient the quantity being regulated by the strength of current and length of wire With a given current and a given resistance the amount of ether vaporised in a unit of time can be readily estimated In practice it is found that the ether vapour reaches the patient at a higher temperature than its boiling point owing to the space above the ether becoming heated by the naked wire *In using the apparatus* I have passed the ether vapour through a rubber tube and fixed the end under a Schimmelbusch mask The subject of intratracheal ether anæsthesia has recently attracted considerable attention which has prompted me to bring forward the above method which ensures in the simplest [illegible] manner the two conditions essential to intratracheal technique these being warm vapour delivered at a constant pressure In cases where active ventilation of the lungs is desired a stream of warm oxygen can be easily added by means of a T-shaped connexion attached to the delivery tube



inter relation of the care of the individual with the care of his environment is shown to be a necessity in educating the young, and for work in this direction to be of real value it must be founded on facts observed and collated The very natural criticism suggests itself that the result of the inspection of school children, unless most carefully made and on some more or less uniform plan, may result in masses of statistical findings having no common points of comparison, and furnishing therefore little opportunity for deriving from the figures indications for practical advance The Chief Medical Officer, with a proper feeling that work done should have its executive outcome, suggests to school medical officers how they can best assist the Board to a comparative study of the data which they obtain, in a way which will not arise from mere records, however complete, of defect and disease He asks them to make a systematic and comparative study in their education areas in regard to the following five points the presence and distribution of disease in childhood, its causes and the conditions favourable to its production, the effects and sequelæ of such diseases and defects, the means of treatment and their results, and the means and methods of prevention, and in an appendix to the report specimen tables are printed as indications to school medical officers how to keep their records with a view to securing uniformity If the indications are faithfully followed, the accumulated records will have a living value, and may help in the interpretation of many obscure points in sociology

Discussing the influence of age and sex upon the physical condition of childhood Sir GEORGE NEWMAN institutes a comparative study, admitting that the classification is arbitrary rather than scientific, between "entrants" and "leavers" When we look at the figures respecting London we have at once the sad circumstance revealed to us that during the period of school the general physique of children does not tend to improve Thus in London "entrant boys show 10 8 and girls 9 8 per cent of poor and bad nutrition while of leavers no less than 14 7 per cent boys and 14 3 girls show the same conditions These figures are supplemented by others dealing with different districts in London and here the size of London stands us in good stead—as a rule that size prevents the discussion of any social problem—because we are able to consider very large populations, equivalent to populations in first class cities both at home and abroad who can be classified as belonging to groups of districts where the standards of comfort and well being are markedly different Taking Bermondsey as an extreme example of a district where deterioration of physical condition takes place during school life we find that of the entrant boys and girls 5 6 and 5 0 per cent respectively show poor and bad nutrition while of the "leavers" in Bermondsey 28 5 per cent boys and [illegible] girls display these defects This is a serious indictment of the environment which Bermondsey is able to provide for its childhood, for the percentage of poor material at the beginning is not excessive In Hammersmith the figures of the "entrants" showing poor and bad nutrition are for boys 5 6 per cent, and for girls also 5 6, while among "leavers" the figures have been transformed for boys to 7 0 per cent and for girls to 12 0, showing the same defects Another borough, which is considered in the same group as Hammersmith, is Holborn, where 5 7 per cent of the boys and 4 4 per cent of the girls show poor and bad nutrition as "entrants," while of the 'leavers" 14 0 per cent, of the boys and 8 8 per cent of the girls show the same defects We have not selected these figures arbitrarily for comparison, but only to show how information obtained methodically and on a uniform pattern cannot fail to be valuable There must be some underlying reason for the fact that the school age has such an ill effect on the girls in Hammersmith and on the boys in Holborn The influence of sex in London as a whole appears to be slightly to the advantage of girls, inasmuch as 10 8 per cent of "entrant" boys and 14 7 of "leaver" boys are reported deficient in nutrition, as compared with 9 8 per cent of "entrant" and 14 3 per cent of "leaver" girls Mr F E FREMANTLE, the medical officer of health of Hertfordshire, in his annual report supplies, however, some figures which give interesting exceptions to the London finding His figures show that at the ages of 5, 7, and 12 years girls are invariably worse off than boys At 5 years the percentages of defect for boys and girls respectively are 2 5 and 2 6, at 7 5 1 and 5 4, and at 12 7 0 and 8 1 A similar finding is recorded in the rural areas of Bedfordshire, though the standard of poorness of nutrition is more severe than in Hertfordshire, the percentages being 23 7 for boys and 25 1 for girls Among purely urban areas the return for Bilston shows the alarming proportion of 63 per cent of senior girls "below normal or bad,' as compared with 38 42 per cent of senior boys Statistics systematically gathered and intelligently read may give us the clue to these obscure discrepancies

In one important direction Sir GEORGE NEWMAN'S report transgressing his own limitations of date, deals with matters of present moment The section referring to the provision of meals for children attending public elementary schools takes notice of the situation as recently as after the outbreak of the war It will be remembered that the Education (Provision of Meals) Act, 1914, was read for the third time on August 4th, 1914, receiving the Royal Assent three days later so that the new legislation arrived exactly when responsibilities of a far reaching sort were certain to be thrust upon the authorities That the dislocation of trade following upon the war would lead to an increase of distress among the poorer classes of children was inevitable, and on the date on which the Act came into force the Board of Education issued a circular letter to all the authorities under its jurisdiction, urging them to make since it is desirable that some consistency should be shown in the methods of abbreviation. Many readers will call to mind abbreviations which seem to be almost hallowed by custom—for example, mag. sulph. or pot. iod.; these are employed so frequently that it would seem impossible to question the intention of the prescriber, and yet both of these may be misread. Quite recently serious results followed from the use of barium sulphide where sulphate had been intended, under the abbreviation "sulph." It is desirable that abbreviations, if used, should be as short as possible, consistently with clear indication of the meaning. It is understood that similar abbreviations are likely to be included in the next issue of the Pharmacopœia of the United States, and there can be little doubt that great convenience would result from the universal adoption of a recognised series of abbreviated titles. Many misapprehensions and misunderstandings might be removed by careful study of the preface, which clearly defines the scope and intention of the principal changes that have been adopted. In the preface it will be found interesting also to note the acknowledgments of assistance received by the Pharmacopœia Committee of the General Medical Council. It is evident that the task of revision was commenced almost immediately after the publication of the Pharmacopœia of 1898, and that this revision has been undertaken by many who unfortunately are not with us to welcome the new volume. Of pharmacists, the late Mr. CHARLES EKIN and Mr. K. J. DOWNES may be mentioned, while from the long list of those who have served on the Pharmacopœia Committee since 1898 the Revising Committee undoubtedly received untold help from the labours of the late Mr. TICHBORNE and Dr. LEECH. It is, we believe, an open secret that Dr. LEECH advised the *rapprochement* with pharmacists which led to the Pharmaceutical Conference, which in time gave place to the Committee of Reference in Pharmacy.

◆

The Physical Condition of School Children[1]

THE Annual Report for 1913 of the Chief Medical Officer to the Board of Education, Sir GEORGE NEWMAN, makes its appearance at the close of 1914, and it may be explained that these dates are not mentioned with intent to imply that the publication is belated. First, the report, although dated as referring only to 1913, covers a year ending on March 31st, 1914; and secondly, the Chief Medical Officer takes into account in his summary the reports of all the school medical officers in the country. There are over 300 areas for Elementary Education in England and Wales, each with a principal school medical officer, and in 223 of these areas schemes of medical inspection have been [illegible] [illegible]. If the local reports reached the Board of Education with punctuality—which is not the case—there is a great work of sifting and collating to be done before any comprehensive lessons can be derived from the mass of material. That punctuality is not always observed in the matter of local reports is indicated by the fact that this year the Chief Medical Officer issues a special request that these documents should be sent in as soon as possible, and not later than the end of March. The general spirit of the report is optimistic, and we commend its perusal to all those people who, when the first results of school inspection began to arrive, deafened us with plaints about the decay of the race. Circumstances in the war now raging may have caused some of these doleful prophets to reconsider their opinions, and this report should prepare many others of them to follow suit, for its whole story is one of quiet progress. Nor is the story, though in a Blue Book, hard to follow. Sir GEORGE NEWMAN has the gift of packing an enormous amount of information into a reasonably sized volume and of arranging his material in accordance with a logical plan. These things make it easy to obtain the facts, to realise their importance, and to appreciate at the proper value their bearing and the fairness of the official estimate. For in this record of the work carried on by the local education authorities of England and Wales, mainly in the field of school hygiene, while along some lines little more than a summary has been given of achievement, along others some clear and pregnant observations provide the public as well as the medical profession with exactly the sort of general principles which should assist in a mutual development of education as a great health factor. It becomes plain that the State machinery to this end is working smoothly, and, if slowly, yet surely.

The two sections of the report possessing the greatest general interest are that which deals with education in relation to infant welfare, and that which deals with the physical condition of school children. These matters claim at the present moment more than ever our close attention. As Sir GEORGE NEWMAN says, "In no direction are the ravages of war more serious or more difficult to replace than in the loss of human lives. Whatever degree of success may attend the nation in the present European war the cost in life must inevitably be heavy. Consequently, the question of the preservation of the rising generation and care for its physical fitness and equipment is of more than ordinary importance." The physical condition of our school children we can all see to be to-day a matter of paramount importance—it was to be for years [illegible] [illegible] nation for [illegible] [illegible] of peace. It is here [illegible] [illegible] be influenced by age, sex, [illegible] conditions, and by the conditions of [illegible] and throughout the [illegible] shown to regard [illegible] [illegible] medical profession our hearty congratulations At the same time we note with pleasure that Dr J Dobbie, F.R S, who acted most efficiently as a scientific referee in chemistry for the new British Pharmacopœia, and Mr Perceval Alleyn Nairne, chairman of the committee of the London School of Tropical Medicine, have received the honour of knighthood and that the Earl of Aberdeen has received the dignity of a marquisate The good work which both Lord and Lady Aberdeen have done in regard to the prevention of tuberculosis is well known to all our readers

EPIDEMIC POLIOMYELITIS AT WEST KIRBY

ELSEWHERE in this week's issue we publish a short record by Dr George Jubb of a small epidemic of acute poliomyelitis at Hoylake and West Kirby, the chief interest of which lies in the fact that for three years in succession small epidemics have occurred in these localities The paucity of the actual number of cases renders the drawing of any definite conclusions somewhat hazardous It may be remarked, however, that the general hygiene of these seaside resorts leaves nothing to be desired, and Dr Jubb has been able to elicit only one fact of possible etiological significance—viz., that all the Hoylake cases had a common milk supply It has been shown in many previous epidemics that the milk supply is not a factor on which any weight can be laid, nevertheless, in view of our ignorance of how the virus spreads, it is well not to overlook any possibility of this sort indeed minor epidemics may furnish data uncomplicated by other and confusing features Dr, Jubb is not in a position to demonstrate any connexion between the milk supply and the disease, but merely records the fact Greater importance should be attached to his remark that the father of the first patient of last summer's epidemic is a medical practitioner who attended two of the cases of 1913 Flexner and his collaborators have shown that the virus of poliomyelitis may remain in an active state in the nasal mucosa of individuals who have not themselves suffered from the disease but who have been in the company of affected patients In one case they were able successfully to inoculate an ape from the washings of the nasal mucosa of the parents of a case whose attack had occurred nine months previously Netter has observed the same phenomenon in some of the French cases of two years ago The fact that the virus may be kept alive by otherwise normal carriers is therefore demonstrated and Dr Jubb's surmise that in this fashion the West Kirby epidemic recommenced is probably correct It is curious that his four cases are all males, and it would be interesting to know what is the sex of the other members of the families that have remained unaffected, though presumably in contact with the infected patients Dr Jubb is not inclined to attach importance to the possibility of the virus being spread by the agency of flies of the house, stable or other variety Experimental work with the stable fly, Stomoxys calcitrans, has been distinctly inconclusive Whether the sand flea can be incriminated is doubtful Observers have frequently been struck by the occurrence of cases of poliomyelitis in association with bathing or wading in the sea and again we do well not to ignore the possibility of some direct connexion in this respect But the endemic poliomyelitis of large cities cannot be thus explained. The evidence at present suggests that apart from human carriers the virus may be kept alive and transmitted by a variety of agencies

A RARE MALFORMATION OF THE HEART

WE publish this week an account by Professor Wardrop Griffith of a rare but highly instructive anomaly of the heart The heart was that of a man, aged 30, with a communication between the right and left ventricles, but the abnormal opening, in place of occupying the site of the pars membranacea septi—the last part of the interventricular septum to be formed—was situated further forwards In this rarer form the infundibulum of the right ventricle communicates with the left ventricle under the aortic cusp from which the right coronary artery opens, in the usual anomaly the "body" of the right ventricle communicates with the left under the "non coronary" cusp of the aorta Professor Griffith has done a service by drawing attention to the fact that the rare or anterior opening is of a totally different nature from the common or posterior opening On the part of the interventricular septum which forms the lower margin of the posterior opening is found the main stalk of the auriculo ventricular bundle the bundle divides and passes down on the sides of the interventricular septum before the site of the anterior opening is reached We may thus infer, from a study of such malformations as that described by Professor Griffith, that the interventricular septum may be regarded as being made up of two parts—a posterior and an anterior Recent investigations into the comparative anatomy and development of the heart have provided an explanation of the double origin of the interventricular septum and the presence of interventricular openings of two kinds The explanation is found in the development of the mammalian right ventricle, it is produced by the fusion of two chambers—the ventricle proper and the bulbus cordis which forms the fourth or final chamber of the heart in lower vertebrate animals The ventricle proper forms only the "body" of the mammalian ventricle its infundibulum is developed from the bulbus cordis The left ventricle is also primarily of double origin but in the human heart and in that of all higher vertebrates the "bulbar" element undergoes—except as a rare anomaly—a complete atrophy The importance of Professor Griffith's communication lies in the fact that it calls attention to the double constitution of the right ventricle The physiology of the infundibulum of the right ventricle has never been studied apart from the ventricle as a whole from the history of the infundibulum we are justified in supposing that it must play a distinctive role in the physiology of the circulation

ROTARY DISLOCATION OF THE ATLAS

IN the *Boston Medical and Surgical Journal* of Nov 26th 1914 Dr John J Morton has reported a case of rotary dislocation of the atlas with certain unusual features A boy, aged 12 years was admitted to hospital complaining of pain in the back and inability to raise the head from a bowed position on the left shoulder Three days previously he was wrestling with a much bigger boy and was twisted violently towards the right while his head was firmly held between his opponent's legs.

preparations to deal with subsequent trouble On August 15th the Board issued a memorandum on the methods to be adopted in providing meals for children at public elementary schools, advising dietaries suitable to the circumstances It is too early to say what effect the thoughtful and even elaborate counsels given in the memorandum have assisted the local authorities in dealing with the situation, but there is no doubt that much has been done to grapple with it There is machinery now in every educational area for feeding all the school children if necessary, but SIR GEORGE NEWMAN'S analyses of the number of children fed and of the number of meals provided show that a great deal remains to be done He reviews all the activities of the authorities in the matter of providing meals for their charges between the year 1906, when the first Act of Parliament for providing meals for children attending public elementary schools was passed, and the present day, and points out that this manifold experience has not yet supplied any satisfactory method for selecting the children to be assisted To mention only one difficulty, the educational authorities have power to recover the cost of meals from parents who are not necessitous, while there is no obligation on the parents to send their children to receive the meals, even though the children have been recommended by the school medical officers as ill nourished subjects who should receive better food What is to stop the unfortunate child being prevented by the parents from attending the free meals? The whole of this section of SIR GEORGE NEWMAN'S report deserves anxious attention, and, indeed, it should all be read, and always from the point of view that in a scheme of State education scientifically conducted our rulers have an opportunity of mitigating at the same time the evils of heredity and the evils of environment

Annotations.

"Ne quid nimis"

MEDICAL PRECAUTIONS IN CASE OF AIR RAIDS

THE probability of shells falling on unfortified coast towns is now obvious to all That bombs may possibly be dropped upon London is clearly present to the minds of the authorities as is shown by the official announcement in the daily papers telling the general population what to do in the circumstances These instructions may be useful for the doctors' families, as for the families of any other citizens But the medical men themselves in the neighbourhood of such a catastrophe know that they have an active duty to perform for their fellow citizens and their country If the reports as to the size number, and high explosive character of the Zeppelin bombs are approximately correct the number of the casualties might be in London far in excess of those which have occurred in less densely populated towns like Antwerp And the wounds would be of a very different character from those with which the police have to deal in ordinary street accident We hear that arrangements are being made, with the full approval of the police, for the speedy despatch of a number of surgeons to the spot in the event of the terrible emergency It may reasonably be hoped that the Zeppelin ships will not succeed in reaching London itself, but it is well to be forearmed, and it is certain that if they did, the most special police regulations would be subjected to a severe test Local medical men would then be of great assistance All medical men are therefore urged to see that their professional cases or bags are well stocked, and especially that a hypodermic syringe, a tourniquet, some dry dressings and some bandages are not missing Then, while their wives and children seek shelter, they should go to the spot of which they will be advised and quietly set to work, in harmony with the police, to render such first aid as may be essential before the wounded are removed to the hospitals or other institutions which, by previous arrangement, will be prepared to receive them, and to which the police will see that they are transported as expeditiously as possible The scheme of preparation has been carefully thought out, it is not the expression of an unreasonable sense of scare, and must not be interpreted by the public as such It represents the desire and intention of the medical profession, in the face of a disaster which may arrive, to meet its terrors and minimise its effects

THE NEW YEAR HONOURS

AMONG the new Privy Councillors is the name of a medical man, Sir William MacGregor, G C M G, C B, who recently retired from the governorship of Queensland He has held a similar position in various parts of the British Empire, and was at one time Government medical officer in the Seychelles and chief medical officer for Fiji Dr Herbert Lethington Maitland, of Sydney, has been made a Knight Bachelor, Major Samuel Richard Christophers, I M S, officer in charge of the Malaria Bureau at the Central Research Institute, Kasauli, and Colonel George William Patrick Dennys, I M S Inspector General of Civil Hospitals in the Central Provinces and a member of the Council of the Chief Commissioner for making laws and regulations, have been made C I E s and Mr John Marnoch, Regius professor of surgery in the University of Aberdeen, has been made a C V O The recipients of the Kaisar i Hind gold medal include Major James Husband, I M S, civil surgeon at Bannu N W F Province and Dr Charles Albert Bentley special officer under the Sanitary Commissioner of Bengal In the new Order of the Military Cross for distinguished and meritorious service awards have been made to Captain H Stewart R A M C, Captain F D Caddell R A M C, Lieutenant C Helm R A M C Lieutenant (temporary) F J Wyler R A M C Captain J F Murphy, R A M C Special Reserve and Captain Kanwar Indarjit Singh I M S In the same honours list it is announced that the Indian Order of Merit of the Second Class has been conferred on Senior Sub Assistant Surgeon Pandit Shanker Das (attached) for cool courage in attending wounded under heavy fire at Neuve Chapelle To all these colleagues whose names are thus added to those whose distinctions we have chronicled from week to week during the conduct of the war, we offer in the name of the what was being made and sent into this country from abroad As Mr Martin rightly points out, there exists this difference in regard to experimental research in relation to medicine at home and abroad, that while in Germany and America no difficulty is placed in the path of scientific research or manufacture, we at home are hampered by numerous restrictions, and it is only with difficulty and at great expense that animals suitable for scientific purposes can be obtained In every town hundreds of animals are annually destroyed without having been of the smallest service to any human being whereas in our laboratories during their passage to euthanasia the same animals might have ministered to the suffering of humanity With Mr Martin s statements as to the hindrance to scientific research caused by the restrictions on the employment of animal life for the purpose we are in agreement, but the desire of the legislature to make the regulations as little oppressive as possible is seen to be sincere We accept also his statement, all the more gladly that the reverse has been so widely said, that we possess a flourishing British chemical industry, and that it is not so much a question of restoring lost trade as that of expanding what we possess and of putting renewed vigour into it and fresh scientific force We are glad to learn that the decadence so freely talked about is only apparent and not real, but it is none the less necessary that we should increase the scope of our activities by admitting into them all the resources of modern skill and knowledge in every detail

Dr George Sigerson has been appointed by the Lord Lieutenant of Ireland to be a Member of the Board of Visitors of the National Museum of Science and Art, Dublin, for a period of five years

Dr S A Kinnier Wilson has been elected a corresponding member of the Philadelphia Neurological Society

LEPER HOUSES AND MEDIÆVAL HOSPITALS[1]

BY CHARLES A MERCIER M D LOND, F R C P LOND, F R C S ENG

LATE PHYSICIAN FOR MENTAL DISEASES, CHARING CROSS HOSPITAL

In the last lecture[2] I said that the leper house partook of the nature of the prison the monastery and the almshouse With the prison aspect I have dealt but at least equally important in the minds of the founders not only of leper hospitals but of hospitals for whatever object, was that the hospital should be carried on as a monastic institution

The Monastic Constitution of the Mediæval Hospitals

Most hospitals had churchmen at their head [illegible] were on the same foundation as a college for priests or for canons regular or secular, and all [illegible] had a monastic or semi monastic constitution The obvious explanation is that in [illegible] when there was no [illegible] so [illegible] to [illegible] the [illegible] of the [illegible] of charitable [illegible] [illegible] such funds to those who had [illegible] and themselves

to live what is now known as the simple life This is the obvious explanation, but I believe that, like most obvious explanations, it is incorrect, or at least insufficient It is scarcely possible for us in these days to realise how large a part in the lives of our forefathers was occupied by the Church It might have been said of the Church, as was said of another matter that—

> 'Twas allotted to man with his earliest breath,
> Attends at his birth, and awaits him at death,
> Presides o'er his happiness honour and health
> Is the prop of his house, and the end of his wealth—

and in the interval it regulated a very large share of his life The chief field of industry was the tilling of the soil, and not only was one third of all the land of this country in the hands of the Church, but at every gathering of the produce of the land the husbandman must set apart one-tenth as tribute for the Church The very calendar was reckoned, not by the days of the month, but by the saints days and the feasts of the Church A date was recorded, not as the 16th of June or the 11th of August, but as the eve of St Alban or the day after the feast of St Lawrence The priest combined in himself all the learned professions, and no undertaking of importance could be effected without him At any rate in rural districts, he was not only the priest but the only available physician and lawyer When the layman was sick the priest heard his confession and exhorted him to benefit the Church by his will Then, that there might be no backsliding, the priest assumed his legal function, and as a lawyer drew his client s last will and testament In his character of physician he then put his patient to death, and finally, resuming his legal functions, he proved the will in the ecclesiastical court The reason why every hospital had a semi monastic foundation was, as I take it, that it never occurred to the pious founder that it could have any other It was as natural, as proper, as inevitable to him to provide a monastic framework for his charity as it is to us to provide physicians and nurses No additional motive was needed, but if one had been needed, it would have been found in the provision, so often made, for a perpetual succession of prayers for the soul of the founder In fact, in some hospitals, notably in that founded by the celebrated Richard Whittington, thrice Lord Mayor of London, this was frankly the main object of the foundation By his will, Whittington founded first a college of priests and clergymen and in the same foundation a hospital for 13 poor people and he strictly enjoined them all, priests clergy and poor alike, to pray daily at all the canonical hours for his soul and that of Alice his wife and at other times, when they were not at church they were to say daily thrice 50 angelical salutations, with the Lord s prayer 15 times and were all to meet daily at the tomb of the founder to say the psalm De Profundis and to invoke the mercy of God on the souls of him and his wife Alice It seems, therefore that Whittington took every precaution that was humanly possible to secure for himself and his wife a prosperous hereafter and it looks as if the charity that he exercised towards the 13 poor began, in a special sense at home

In many hospitals the same regulations as to attendance at divine service at all the canonical hours are enjoined on the inmates and in addition they are exhorted to their private devotions which were by no means to be perfunctory or neglected on punishment which would now be looked on as

---

[1] [illegible]

[2] [illegible]

Immediately afterwards his head was inclined towards the left shoulder and could not be brought back to the middle line He suffered from severe pains in the neck which prevented him from sleeping for two nights Directly after the injury he could not speak aloud He had considerable difficulty in swallowing and took nothing but liquids On examination he appeared to be in much pain and spoke in a scarcely audible whisper. His head was fixed in such a position that the left cheek rested on the corresponding shoulder. He supported his forehead with his left hand and cried with pain if the hand was removed. Passive movement of the head was very painful The spines of the axis, seventh cervical, and first dorsal vertebræ were prominently felt and there was a depression below the occiput The transverse process of the atlas could not be felt in the normal position on either side The mouth could not be opened sufficiently to allow examination through the pharynx. The reflexes were exaggerated on both sides A radiogram taken from a lateral position showed a displacement between the atlas and axis, an eighth cervical vertebra, and an appearance which caused suspicion of a fracture of the atlas Under anæsthesia an attempt was made to reduce the deformity Examination then showed a prominence on the right side of the pharynx on a level with the soft palate, which was thought to be the transverse process of the atlas The head was extended on the body and gently rotated toward the right At the same time an assistant pressed on the prominence in the pharynx. The head easily came to the middle line without a catch or click of any kind. The position was maintained by a bandage around the head, neck, and chest On regaining consciousness the pain had disappeared and normal phonation was restored. At the end of two weeks the bandage was removed and passive movement of the head was possible without restriction or pain A skiagram showed the atlas and axis in normal relation. At least 14 cases of uncomplicated rotary dislocation of the atlas have been recorded and many cases associated with fracture of the odontoid process or arch of the atlas Aphonia has not been previously reported as a symptom of rotary luxation, though it has been observed in other forms of dislocation of the atlas and in dislocations of the upper cervical vertebræ It appears to be due to injury of the vagus nerve Supporting the head with the one or both hands, difficulty in opening the mouth, and dysphagia have been observed in cases of dislocation of the atlas The last of these symptoms has been attributed to injury of the upper cervical nerves

THE POSITION OF FINE CHEMICALS

AN authoritative estimate of the part played by this country in chemical manufactures was given in a paper recently read before the Newcastle section of the Society of Chemical Industry by Mr W H Martin, J P, F R S E, F C S, a well known chemical manufacturer After expressing the opinion that there is absolutely no more reason for the Government either directly or indirectly to subsidise or assume control of the dye manufacturing industry than of any other, he stated his impression that there are many important manufacturers in this country who will quickly cope with the necessities of the consumers [illegible] alluded forcibly to the ignorance which pre as to what our nation does accomplish in the way of manufacturing chemicals of prime importance, and nowhere is this more apparent, he added, than in the region of medical substances With regard to morphia, for example, regret has been expressed that the supply comes from Germany As a matter of fact, practically the whole supply for Europe, including Germany, is manufactured in Great Britain. Quinine, again, though largely made on the continent, is produced in quantities in this country which are far more than is required for the whole of the British Empire. The case of caffeine is interesting Mr Martin reminds us that it was first made by an Edinburgh firm and exhibited by them at the Vienna exhibition of 1873, after that, when the demand increased, it was made in Germany for a considerable period, until our Government allowed the waste tea which came into the London docks to be denatured Since that step was taken caffeine has been made to an enormous extent in this country In respect of other alkaloids produced in this country, Mr Martin quoted the following words of a manufacturer "On the general question of alkaloids we may assure you that in scarcely any instance have we ourselves been outstripped by Germany in such products as we have ever seriously taken up On the contrary, before the war Germany was our best customer, and we venture to think this is a fairly good answer to a great deal of the loose talk at present indulged in by writers to the newspapers on what is sometimes described as the decadence of British industries" Apparently no chloroform comes from Germany at all, but it is made there for home use, while British chloroform is exported to a considerable extent to all parts of the world The early success of certain synthetics, notably antipyrin, has proved, Mr Martin thinks, a snare to German science "Hardly a month passes," he said, "but that some new substitution compound with a trivial name to indicate its alleged medicinal properties, and a scientific name intended to suggest profound research, is introduced to English medicine" For a time, he allows, we shall be placed at a great inconvenience with respect to a few remedies which are of value, but he has been assured by one of the oldest aniline manufacturers in this country that there are no difficulties in making these drugs by anyone who understands the business, that they are being made, that their output is being increased enormously, and that probably new manufacturers are introducing synthetic medicinal products With regard to scores of other synthetic remedies (so called) he is of the opinion that the sooner they are consigned to the oblivion from which German enterprise brought them the better for science and medicine Mr Martin in the closing sentences of his interesting paper gave a very suggestive example of the severe handicap experienced in this country by the restrictions placed on experiments upon animals His firm were the first to manufacture animal extracts, following the original suggestions of Brown Sequard At the instance of Professor George Murray they prepared above all, thyroid extract But in the case of suprarenal extract they were soon outdistanced by the importation of the active principle from America and Germany This product was standardised by physiological experiment, as is necessary in order to guarantee its activity and purity Delay in developing an equally active and pure extract here was caused by the restrictions of the Government, but eventually a licence was granted and a product was put upon the market equal to was to have ninepence (about 20s now) per week, and the master, who was to be a priest, six marks per annum

Lepers' Allowances of Food and Clothing

In several hospitals the amount and quality of the food and clothing allowed to the inmates was minutely specified, and in some was extremely liberal Thus at the Leper House of St Mary Magdalen at Ripon (early twelfth century) every leper was allowed a garment called rak and two pairs of shoes yearly, and every day a loaf fit for a man s sustenance, and half a pitcher of beer, a portion of flesh on flesh days and three herrings on fish days In process of time, no lepers coming to the hospital, the charity was changed to a dole at the feast of St Mary Magdalen to every poor person coming, of one loaf worth a halfpenny, the quarter of corn being worth 5s, and one herring The loaf would now be a tenpenny one At the great Leper House of St Julians (1146) at St Albans the allowances were extremely generous Each leper had every week seven loaves, five white and two brown, and every seventh week 14 gallons of beer, and on each of the great feasts of the Church one loaf, one jar of beer, or a penny for the same At Christmas each leper received 40 gallons of good beer, or 40 pence for the same, and his share of two quarters of pure and clean corn At the feast of St Martin each leper was to have a pig, on the feast of St Valentine a quarter of oats, on the feast of St John the Baptist two bushels of salt, on each Wednesday in Lent bolted corn of the weight of one of their loaves, and in addition the following sums of money On each of the great feasts of the Church one obolus, at the feast of St Julian and at the feast of St Alban one penny, at Easter one penny, which is called flavonespani, on Ascension Day one obolus for buying potherbs, on the feast of St John the Baptist 4s for clothes at Christmas 14s divided among them for their fuel during the year and at the feasts of Easter and Michaelmas 30s 5d to be divided between them equally

At Shireburn Hospital in Yorkshire (1311), for 65 lepers the daily allowance of each leper was a loaf weighing five marks and a gallon of ale to each and betwixt every two one mess or commons of flesh three days in the week, and of fish, cheese or butter on the remaining four On high festivals a double mess, and in particular, in the feast of St Cuthbert in Lent, fresh salmon if it could be had if not other fresh fish, and on Michaelmas day four messed on one goose With fresh fish, flesh or eggs a measure of salt When fresh fish could not be had, red herrings three to each mess or cheese or butter by weight or three eggs During Lent each had a razer of wheat to make frumenty and two razers of beans to boil some times green meat or onions and every day except Sunday the seventh part of a razer of bean meal but on Sunday a measure and a half of pulse to make gruel Red herrings were prohibited from Pentecost to Michaelmas and at Michaelmas each received a razer of apples

The lepers had a common kitchen and a common cook and fuel and utensils for cooking—viz a lead two brazen pots a table a large wooden tub for washing or making wine a laver two ale vats and two bathing vats They were provided with fire candles and all necessaries the old woman who attended on the sick had every week three wheaten loaves and one mess of flesh or fish Each leper had a yearly allowance for his clothing of three yards of woollen cloth, six yards of linen, and six of canvas, and the tailor had his meat and drink the day on which he came to cut out their clothes Even the grave digger had his meat and drink when a brother or sister was buried From Michaelmas to All Saints two baskets of peat were allowed on double mess days, and four baskets daily from All Saints to Easter On Christmas Eve four Yule logs, each a cartload, with four trusses of straw, and so on, and once a year every leper received 5s 5d in money

Hospital for Persons Losing their Memory

From time to time we read in the newspapers accounts of persons found wandering in the streets, having entirely lost their memories, and knowing not who they are, where they live, or even their own names We are apt to think that this is a purely modern occurrence, and that it is due in some unexplained way to the intensity of the struggle for life in these days, and the rapid rate and high pressure at which we live It seems, however, that it was not unknown five centuries and a half ago, for in 1371 Robert Denton purchased for 40s of King Edward III a licence to found a hospital in a house of his own, in the parish of Berking Church in London, "for the poor priests and other poor men and women in the said city who suddenly fell into a frenzy and lost their memory, to reside in till cured." For some reason, perhaps for a lack of patients answering this description, Robert Denton afterwards changed his mind, for we find that Richard II, in the second year of his reign, by charter allowed him to annex his charity, and another messuage in the parish of St Laurence Pountney, to the Hospital of St Catherine by the Tower

Sources of Revenue

The liberal allowances made to so many inmates in the larger hospitals imply considerable revenues, and the revenues of some of the mediæval hospitals were very large They were derived for the most part from endowments, though then as now a portion of the revenues were obtained from alms, which we now entitle voluntary contributions, economically making eight syllables do the work of one The endowments were very varied in character, consisting for the most part of land or of the appurtenances of land, such as houses, mills, manorial rights, free pasturage, rights of lopping and topping or collection of firewood, fish ponds, and so forth Sometimes, however, the endowment was of a franchise, more or less valuable The most valuable of these was the right to hold an annual fair, which was bestowed upon, for instance, St James s Hospital near Westminster All leper houses were by a bull of Pope Alexander III freed from the obligation of paying tithes Some, such as the great house at Burton Lazars were exempted by royal grant from all sorts of taxes and contributions Some received tolls for passage by land or by water or exemption from tolls Thus Henry III gave to the Maison Dieu at Dover the tenth of the profits accruing to him by passage of the said port and Magnus, king of Man and the Isles exempted the ships belonging to Conyngesheved Hospital in Lancashire from paying any dues in the ports of his dominions

The bounty of some benefactors was so generous that they granted freely what did not belong to them Thus King Henry III granted to the Hospital of St John without the Gate at Oxford severe, was inflicted for negligence The hospital was, in fact, a fourth order of religious house, ranking after the college, as the college ranked after the priory, and this after the abbey, and any of these might be superior in wealth and influence to some neighbouring foundation of superior dignity The hospital usually, though not invariably, had some charitable function tacked on to its monastic purpose Most hospitals, especially after the cessation of leprosy, were almshouses for the support of the poor and the infirm, many were for the relief of travellers, and others for the care of the sick

Hospitals Founded in the Middle Ages

The first hospital founded in England was established early in the tenth century at Flixton in Yorkshire by one Acehorne Its government was entrusted to an alderman and 14 brothers and sisters, and its purpose was the preservation of travellers, that they might not be devoured by wolves and other wild beasts abounding there Curiously enough, the second English hospital, which was founded shortly afterwards in the reign of the same king, Athelstan, was also connected with wolves, for it was endowed by the King with Peter corn—that is to say, one sheaf of corn from every plough throughout the bishopric of York These sheaves came into the King's hand by gift from the diocese on condition that he should destroy the wolves, which were so numerous in those parts that they devoured the cattle, and they were accordingly quite extirpated by King Athelstan Of this hospital, which was first dedicated to St Peter, and afterwards, on its refoundation by King Stephen to St Leonard, the ambulatorium still exists at York It was, at the visitation in the time of Henry VIII, the wealthiest hospital in England, its revenues exceeding those even of St Bartholomew's in Smithfield St Leonard's still remains a charitable foundation, and still supports 21 poor persons in place of the 224 that it maintained at the height of its prosperity

These appear to be the only hospitals founded in this country before the Conquest, but ten years after that event the Pilgrims' House was founded in connexion with Battle Abbey, and two others, St Nicholas at Lewes and St Wulstan at Worcester, were founded in the reign of the Conqueror A third, St Nicholas at Nantwich, was founded in the year of his death, but what the objects of these hospitals may have been cannot now be known, for no record remains It was Lanfranc, however, the great Archbishop of William, who founded in the succeeding reign the first hospitals for the sick ever established in this country These were the Leper House of St Nicholas at Harbledown, near Canterbury, and the Hospital of St John the Baptist without the North Gate of Canterbury for poor men and women "suffering from several diseases"—that is to say, from diseases other than leprosy Both these foundations are actively dispensing charity at the present day, though they are no longer devoted to their original purpose of receiving the sick These six hospitals were all that we know of that were founded in this country in the eleventh century, and all of them were founded in the last 34 years of that century

In the next 50 years there were founded 46 hospitals, of which 24 were leper houses, and the whole of the twelfth century saw the foundation of 168 hospitals, including 80 leper houses In the wonderful thirteenth century the foundation of leper houses had begun to slacken, in spite of the increase of the population, the number being only 75, but 167 hospitals for other purposes were founded in that century, the combined number being 242. In the middle of the fourteenth century occurred the Black Death, which swept off from a half to two thirds of the population, and accordingly we find that while 111 hospitals (42 of them leper houses) were founded between 1300 and 1350, only 67 (including 20 leper houses) were founded in the remainder of the century The falling off of leper houses was due in great part, no doubt, to the diminution of leprosy, for in the next half century no leper house at all was founded, and in the rest of our history the number was not more than ten However, for some reason the rate of foundation of hospitals was not maintained, only 96, including five leper houses, being founded in the fifteenth century, at the conclusion of which the Middle Ages may be considered to have come to an end The total number of hospitals founded in this country in the Middle Ages was, as far as is known, at least 691, of which 224 were leper houses This provision for the poor and sick was, of course, in addition to the very large amount that was provided by the monasteries and friaries, and in proportion to the population was certainly generous

The Objects of the Foundations

The objects of these foundations were various, and some of them strike us as whimsical They were sometimes purely monastic, but usually there was some charitable purpose tacked on to the monastic constitution of lay brothers and lay sisters, and most of them were wholly or in part almshouses In many cases the recipients of the charity were the poor and infirm, in one case poor, sick, and lame, in one case poor distressed people, blind, and other poor persons, in one for the poor, the sick, and for entertaining travellers Some hospitals were merely for the dispensation of doles, either of money or of food At Billeswicke, near Bristol, the foundation provided that a hundred poor men were to be fed daily for ever, and each of the poor was to have a loaf of the weight of 45 shillings and made of equal parts of bean flour and barley He was to have also a sufficient quantity of pottage made with oatmeal This was in 1229 Or the dole was of money Queen Eleanor, the dowager of Henry II, directed that at St Catherine's by the Tower (after the usual religious services had been satisfied) every day in the year till the 16th of November there should be given to 24 poor one halfpenny each, equivalent at the present day to about fifteen pence, and on the 16th of November, being the day on which King Henry died, one halfpenny each to a thousand poor In many cases the hospitals provided lodging for poor persons, sometimes alone, sometimes with board and clothing, sometimes with a pecuniary allowance instead of board or of clothing, or in addition to both Thus, William Elsing, the founder of Elsing Spittle (1329), provided that "in regard that many poor people got their bread by the alms of good Christians, yet had no lodging to entertain them," there should always be beds and rooms for one hundred blind and other poor wretched persons This was the first hospital founded in this country specifically for the blind At Newstede, near Stamford in Lincolnshire (twelfth century), a hospital was founded for seven infirm poor persons, who were to reside there and to have necessary food and clothing At St Bartholomew's at Oxford, there were to be six infirm brothers and two sound to take care of its business, and each brother

EDINBURGH ROYAL INFIRMARY.—The report by the managers of the Royal Infirmary, Edinburgh, shows that [illegible] of in-patients during the year ending October 1914 was 12,115. Of these 4205 were [illegible] 7 [illegible] 77 and the [illegible] 706 [illegible] treated there had passed through the infirmary wards a considerable number of recruits who suffered from varicose vein, hernia, and other conditions calling for operative treatment before these men could be accepted for military service. The surgeons were still treating cases of this [illegible] and in fact they are being admitted daily. Sir Joseph [illegible] has been relieved of his [illegible] the [illegible] Hospital [illegible] Dr [illegible] John [illegible] The [illegible] John [illegible] to [illegible] to the [illegible] the garden of the Jews at Oxford but he generously reserved to the owners sufficient land wherein to bury their dead King John gave to the poor of St Giles's Hospital at Shrewsbury both hands full of every sack of corn brought into the market there, and one handful of every sack of flour The Knights of St John of Jerusalem petitioned the King for the grant of the tithes of the parish of Boston in Lincolnshire, and the King was graciously pleased to rob the parish church accordingly, and to make the Knights of St John receivers of the stolen goods

Some forms of charity were distinctly economical, and were designed to benefit the hospitals at a minimum of cost to the benefactor For instance, King Henry III granted to the Hospital of St John Baptist at Coventry free licence to the brothers and sisters to go or send any messengers abroad to beg for alms during the space of seven years, and enjoyned all persons to defend and assist them The most thrifty bequest ever made to any hospital was that made by former Kings of England, and confirmed by Henry IV, to the Hospital of St Giles near Maldon in Essex The keeper or master thereof was to have towards the maintenance of the leprous burghers of the said town the forfeitures of bread, ale, and fish that were not good and wholesome in the said town of Maldon. It seemed to me very unlikely that a device of such a thrifty and economical character could have been originated by the unaided genius of the English, and I looked to a more northern source for the original of the plan, nor did I look in vain It was provided, I find, by the Parliament of Scone, in 1386, that "gif ony man bring to the markit corrupt swine or salmond to be sauld, they sall be taken by the Bailies and incontinent without any question at all sall be sent to the lipperfolke, and gif there be no lipperfolke, they sall be destroyed uterlie"

The Ruin of the Mediæval Hospitals

In the course of time, as leprosy died out in the country, the leper houses were put to other uses In some, the endowment was faithfully applied to other charitable uses Thus St Mary Magdalen at Ripon, when no more lepers came there, was devoted to the relief of wayfarers, especially begging clergymen, meaning, no doubt, Franciscan friars, that they should be therein relieved one night with food and a bed, and be gone in the morning This hospital also dispensed doles to the poor But in many leper houses, and other hospitals also the successive visitations ordered from time to time by different kings and bishops disclosed gross abuses Hospitals intended for the poor dispensed their hospitality to well to do people who paid for their accommodation, thus reminding us of the similar transformation of the great public schools and of the hospitals founded in modern days for the reception of the needy insane The master or warden often became an absentee, and drew his emoluments without performing any duties, so that the hospital fell into decay and neglect, and not only in this but in holding a plurality of such posts the masters of hospitals emulated the parochial clergy Not only was the income of the hospital spent for the private benefit of the officials, but its capital was raided for the same purpose, so that in less than 40 years the income of St Leonard's at York diminished by nearly two thirds

But the ruin of the mediæval hospitals was the eat spoliation by Henry VIII He began with the small monasteries, then the great monastic bodies were destroyed, and at length his greed devoured almost every charitable institution in the country Many of the hospitals were affiliated to religious houses, and these were the first to be robbed There is no doubt that the monastic constitution of the hospitals, which had been for centuries their safe guard, was now the cause and even the pretext of their ruin We have seen that many hospitals were in fact collegiate bodies of priests, some with but little charitable function, and some with none at all Hence they were involved in common ruin with the formally monastic bodies, and the wealth of both went into a common fund for the enrichment of court parasites

Many municipalities, concerned at this robbery of the poor, petitioned the king to be allowed to re establish the charities that he had destroyed, and in some instances his Grace was graciously pleased to permit them to make good out of their own corporate funds or out of their own pockets, the funds that he had stolen In this way were re established the great Hospitals of St Bartholomew in Smithfield and St Thomas in Southwark, St Mary of Bethlehem in Moorfields, and many another hospital throughout the country St Bartholomew's is still a great and wealthy hospital, with large revenues, and livings in its gift, but it is shorn of most of the ample privileges bestowed upon it by Henry I, who declared that it should have all the privileges and immunities that any church in England enjoyed, and that it should be as free as his own crown, and accordingly he released it from shire and hundred, from suits and pleas and murders and geld and Danegeld, and hidage and assize, and works at castles or rebuilding of them or of bridges, or enclosing of parks, and carrying of wood and other things, as also from ferdwit, hengwit, wardpan, averpan, blodwite, futwite, childewite, hundredespan, tethinepan, muchbryche, mischeninge, schewinge, fridsoore, westgeiltheof, wardwithe, utterne, fowinge, and withfange

---

THE Governor of Mauritius, in a telegram to the Secretary of State for the Colonies received at the Colonial Office on Jan 4th states that 10 cases of plague were reported for the week ended Dec 31st, all of which were fatal.

TINCTURE OF OPIUM AND THE POISONS SCHEDULES —At an inquest held by Dr F J Waldo at Southwark upon the body of a woman who had died from heart failure following pneumonia it came out in the evidence that the deceased had been in the habit of consuming four or five ounces of tincture of opium weekly In connexion with this and with observations made as to the ease with which narcotics could be purchased, the attention of the jury was called by the coroner to the fact that after Jan 1st, 1915 tincture of opium would find itself transferred from the second to the first schedule of the Pharmacy Act The drug as sold would be stronger owing to the issue of the new edition of the British Pharmacopœia, and the signature of the poisons book at each transaction and other precautions and formalities associated with the sale of drugs in the first schedule might be expected to have an effect upon the number of deaths from narcotic poisoning Dr Waldo in summing up explained and dwelt upon this point which druggists will have to bear in mind and also made observations upon the frequency with which in cases of death inquired into by him the habit of taking drugs had been contracted through medical men prescribing them in oriental countries and through the use of them being continued by the patients afterwar is without medical advice In other instances the habit was first acquired through the easy purchase by the public of quack compounds and advertised remedies' for disease

University of London Contingent Senior Division Second Lieutenant Bernard F Armitage, from the Cambridge University Contingent, Senior Division Officers Training Corps, to be Second Lieutenant, for service with the Medical Unit

THE NEW YEAR HONOURS

Major Samuel Rickard Christophers I.M S, and Colonel George William Patrick Dennys I.M S, have been made C I E s and Major James Husband I M S, has received the Kaisar i Hind gold medal In the new Order of the Military Cross for distinguished and meritorious services awards have been made to Captain H Stewart, R A M C, Captain E D Caddell, R A M C, Lieutenant C Helm, R A M C Lieutenant (temporary) E J Wyler, R A.M C Captain T F Murphy R A M C Special Reserve, and Captain Kunwar Indarjit Singh, I.M S The Indian Order of Merit of the Second Class has been conferred on Senior Sub-Assistant Surgeon Pandit Shanker Dass (attached) "for cool courage in attending wounded under heavy fire at Neuve Chapelle"

DEATHS IN THE SERVICES

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

In the 97 English and Welsh towns with populations exceeding 50 000 persons at the last Census, 9261 births and 7395 deaths were registered during the week ended Saturday, Jan 2nd The annual rate of mortality in these towns, which had been 15 7, 16 1, and 14·0 per 1000 in the three preceding weeks, rose in the week under notice to 21 3 per 1000 of their aggregate population, estimated at 18 120 063 persons in the middle of 1914 During the 13 weeks of the quarter just ended the mean annual death rate in these towns averaged 14·9 against a corresponding rate of 15 3 per 1000 in London The annual death rate last week ranged from 8 6 in Bournemouth 10·6 in Oxford, 12 2 in Acton 12 3 in Hornsey, 13·0 in Lincoln and 13 1 in Darlington to 27 5 in Liverpool 27 7 in Newcastle-on-Tyne, 30 8 in Wigan 32 1 in St Helens and 33 1 in Grimsby

The 7395 deaths from all causes were 2513 in excess of the number in the previous week and included 575 which were referred to the principal epidemic diseases against 455 and 411 in the two preceding weeks Of these 575 deaths, 263, resulted from measles, 89 from diphtheria 86 from infantile diarrhoeal diseases 50 from whooping cough 31 from scarlet fever, and 20 from enteric fever, but not one from small pox. The mean annual death rate from these epidemic diseases was equal to 1 7 against 1 2 per 1000 in the previous week The deaths attributed to measles which had been 181, 210 and 175 in the three preceding weeks rose to 259 last week and caused the highest annual death rates of 3 1 in Newcastle on Tyne 3 7 in Plymouth and in Merthyr Tydfil 4 1 in St Helens 4 3 in Huddersfield, 5 1 in Wigan 5·5 in Devonport and 8·0 in Grimsby The deaths referred to diphtheria which had been 62 70 and 66 in the three preceding weeks rose to 89 last week and included 26 in London 5 in Birmingham 4 each in Liverpool and Cardiff and 3 each in [illegible] Manchester, Bradford, Sheffield and [illegible] The fatal cases of diarrhoea and enteritis among infants under 2 years which had been 71 51 and [illegible] in the three preceding weeks rose to 86 last week of which 27 [illegible] in London 7 in Liverpool and 6 each in [illegible] and Manchester The deaths attributed to [illegible] which had steadily increased from 35 to [illegible] in the [illegible] weeks further rose to 50 last week

London Fever Hospital, which had declined from 5035 to 4583 in the five preceding weeks, had further fallen to 4503 on Saturday last, 436 new cases were admitted during the week, against 504 451, and 348 in the three preceding weeks These hospitals also contained on Saturday last 1686 cases of diphtheria, 70 of enteric fever, 59 of measles and 40 of whooping-cough, but not one of small pox. The 2050 deaths from all causes in London were 941 in excess of the number in the previous week, and corresponded to an annual death rate of 23 7 per 1000 The deaths referred to diseases of the respiratory system, which had been 316, 314, and 270 in the three preceding weeks, rose to 562 in the week under notice, and were 282 in excess of the number recorded in the corresponding week of last year

Of the 7395 deaths from all causes in the 97 towns, 299 resulted from different forms of violence and 727 were the subject of coroners' inquests, while 1915 occurred in public institutions The causes of 80, or 1 1 per cent of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on Tyne, Salford, and in 66 other smaller towns Of the 80 uncertified causes, 20 were registered in Liverpool, 19 in Birmingham, 6 in London, 4 in Sheffield, and 3 each in Stoke-on Trent, Bootle, and Preston

HEALTH OF SCOTCH TOWNS

In the 16 largest Scotch towns 952 births and 791 deaths were registered during the week ended Saturday, Dec 26th, 1914 The annual rate of mortality in these towns, which had been 18 3, 17 7, and 18·0 per 1000 in the three preceding weeks was again 18·0 per 1000 in the week under notice During the first 12 weeks of last quarter the mean annual death rate in these towns averaged 16·5, against a corresponding rate of 14 4 per 1000 in the 97 large English towns Among the several towns the death rate in the week ranged from 5 1 in Kirkcaldy 10 7 in Perth, and 10 8 in Hamilton to 19 8 in Glasgow, 20 7 in Greenock, and 22 2 in Dundee and in Aberdeen

The 791 deaths from all causes were equal to the number in the previous week, and included 77 which were referred to the principal epidemic diseases, against 76 and 81 in the two preceding weeks Of these 77 deaths, 23 resulted from whooping-cough, 16 from diphtheria, 15 from scarlet fever 12 from infantile diarrhoeal diseases, 5 from measles, and 1 from enteric fever, but not one from small pox. The mean annual death rate from these diseases was equal to 1 8, against 1 2 per 1000 in the 97 large English towns The deaths attributed to whooping-cough which had steadily increased from 7 to 35 in the six preceding weeks, declined to 28 of which 21 were registered in Glasgow and 5 in Dundee The deaths referred to diphtheria which had been 20 16 and 9 in the three preceding weeks, rose to 16, and included 5 each in Glasgow and Aberdeen and 2 each in Edinburgh and Dundee The fatal cases of scarlet fever which had been 15 14, and 17 in the three preceding weeks fell to 15, and included 8 in Glasgow and 5 in Aberdeen The deaths of infants (under 2 years) attributed to diarrhoea and enteritis which had been 10 8 and 15 in the three preceding weeks fell to 12, of which 8 belonged to Glasgow The 5 deaths referred to measles were 2 in excess of the average in the earlier weeks of the quarter and comprise 4 in Dundee and 1 in Aberdeen The fatal case of enteric fever occurred in Glasgow

The deaths referred to diseases of the respiratory system, which had been 163 154 and 169 in the three preceding weeks, further rose to 175 in the week under notice, 36 deaths resulted from different forms of violence, against 23 and 35 in the two preceding weeks

In the 16 largest Scotch towns with an aggregate population estimated at 2,293 200 persons at the middle of 1914, 1035 births and 893 deaths were registered during the week ended Saturday Jan 2nd The annual rate of mortality in these towns which had been 17 7 18·0 and 18·0 per 1000 in the three preceding weeks further rose to 20·5 per 1000 in the week under notice During the 13 weeks of the quarter just ended the mean annual death rate in these towns averaged 16 8 against a corresponding rate of 14·9 per 1000 in the 97 large English towns The annual death rate last week ranged from 7 7 in Perth 8 8 in Kilmarnock and 8·9 in Kirkcaldy to 23 9 in Glasgow, 27·4 in Greenock and 30 2 in Dundee

3rd West Riding Field Ambulance Herbert Harry Emmerson (late Captain, West Riding Divisional Engineers) to be Captain

3rd London General Hospital Major Arthur E J Barker is seconded Major James E Lane is restored to the establishment

West Lancashire Casualty Clearing Station Captain George C E Simpson, from 2nd West Lancashire Field Ambulance, to be Captain

1st Home Counties Field Ambulance Captain Thomas H Peyton to be Major (temporary) John Samuel Ward to be Lieutenant

2nd Home Counties Field Ambulance Captain George T Willan to be Major (temporary)

3rd Home Counties Field Ambulance Captain Hector G G Mackenzie to be Major (temporary) To be Lieutenants Milward Cecil Hayward, Henry Wood Wier (late Cadet, Edinburgh University Contingent Senior Division, Officers Training Corps), and Edgar William Matthews

2nd Northumbrian Field Ambulance To be Lieutenants Thomas William Crowley and Arthur Edwin Tait

1st Wessex Field Ambulance Captain Francis D Blandy, from Attached to Units other than Medical Units, to be Captain

4th Northern General Hospital Basil Hugh Campbell Lea Wilson to be Captain, whose services will be available on mobilisation

Sanitary Service Lieutenant-Colonel and Honorary Surgeon Colonel William Robert Smith, retired list, Territorial Force, to be Lieutenant Colonel (temporary)

East Lancashire Casualty Clearing Station Lieutenant Thomas B Wolstenholme to be Captain (temporary)

2nd East Anglian Field Ambulance Arthur William Hayward to be Lieutenant

3rd East Anglian Field Ambulance Lieutenant Leonard R Toswill to be Captain (temporary) To be Lieutenants Laurence Henry Hutchins and Edward Coomber Hobbs

Attached to Units other than Medical Units —To be Majors (temporary) Captain George P Chappel and Captain William G Sutcliffe Lieutenant Charles S Wink to be Captain (temporary) To be Captains Surgeon Captain Ernest Solly, retired list (late 5th Battalion, The Prince of Wales's Own (West Yorkshire Regiment)), and Lieutenant Arthur Scott Turner To be Lieutenants Norman Preston Laing, Ralph Austin Burditt, John Herbert Jordan Samuel Rutherford Robert Lyall Guthrie, Frederick Hunton Tom Ramsden Kenworthy (late Cadet Corporal, Leeds University Contingent, Senior Division, Officers Training Corps), George Eustace James Hornidge Chauncy, Frank Greenhalgh Prestwich (late Second Lieutenant, 7th Battalion, the Lancashire Fusiliers), and Percy Herbert Burton

Officers Training Corps

Royal College of Surgeons in Ireland Contingent Senior Division Second Lieutenant John S Pegum to be Lieutenant (temporary) to make sure that no corpses remained unburied Imperfect burials are a source of great danger by polluting springs and wells For a long time the inhabitants must use only boiled water or water sterilised by the addition of hypochlorite of lime The graves must be visited and covered with lime, and should even be surrounded by a deep trench containing lime The fields of battle also must be sprinkled with disinfectants for they are still covered with débris of all kinds The dwellings that have been occupied by the enemy have the floors of the houses and the soil of the garden still strewn with foul débris The pollution of the waters and the dust raised in cleaning up are also to be feared The Bureau of Hygiene in the Ministry of the Interior has given the prefects the necessary instructions Rigid surveillance of food stuffs, milk and meat, must be practised For the rebuilding of the destroyed dwellings it will be necessary at first to raise shelters, for often the basements are all that remain for those who return Later, when the villages are rebuilding it will be necessary to watch the cubic air space allowed for the rooms, and the height of the buildings, and to see that acknowledged necessary modifications are introduced Attention must also be paid to prophylaxis and treatment of disease, and to disinfection, for epidemics are especially to be feared among those in a lowered state of health Attention to these matters is urgently demanded

A Gift in Memory of Dr Reymond

Madame Reymond, widow of the Senator Dr Reymond, a médecin major of the 1st Class, who was mortally wounded during an aeroplane reconnaissance[1] has offered to the Army the flying machine with which that heroic officer practised during peace time The offer has been accepted

Obituary Notes

Professor Alfred Fournier died recently at the age of 81 During his long career he added lustre to the chair of the dermatological clinic at the Hôpital Saint Louis A pupil of Ricord, he devoted himself to the study and treatment of syphilis His descriptions of this disease, hereditary or acquired are perfect His entire teaching concerning the effects of the disease on the different organs and especially on the nervous centres remains correct to this day He pointed out the specific character of locomotor ataxy and established the certainty of a similar origin for progressive general paralysis By making known their origin Fournier showed how to avoid them At the Hôpital Saint Louis he founded a school organised a remarkable museum and collected a huge number of precious specimens —Last week also died another highly esteemed medical man

CRIMINAL ABORTION AND PROFESSIONAL SECRECY

To the Editor of THE LANCET

SIR,—In your last issue you raised a very important and delicate question in a leading article relating to the action of a medical practitioner as regards cases of abortion which may come under his professional care In considering this subject it is well to bear in mind that abortion from natural causes is an extremely common occurrence, and that cases of criminal abortion are fortunately of rare occurrence Every medical practitioner attending a case of abortion is perfectly justified in regarding the case as one of natural abortion unless he has definite objective evidence to the contrary, which he can see for himself without asking any questions In attending a case of abortion where there is no conclusive objective evidence of criminal interference the medical practitioner will be wise to regard the case as one of natural abortion, and any questioning on his part as to the possibility of any criminal cause is most strongly to be deprecated It is undoubtedly the medical man's duty to do the best he can for his patient, and any action on his part in the nature of detective inquiry is to be condemned The medical practitioner will wisely refrain from putting questions to his patient or receiving information from her which will throw upon him the difficult burden of "professional secrecy"

If a patient desires on her own account to disclose certain facts it would be wise for the medical practitioner to caution his patient, and to allow her to take such steps on legal advice as she thinks fit, provided, of course that her health is not endangered There is no need for the practitioner to be a party to these proceedings

A class of case sometimes occurs where the medical practitioner cannot play a passive part I refer to cases of abortion where there is conclusive objective evidence of criminal interference Several such cases have come to my notice Examples of such cases are as follows Visible perforating wounds of the cervix uteri or of the roof of the vagina Marked signs of the action of a corrosive agent on the cervix uteri or vagina Perforating wounds of the uterus or vagina revealed at operation on the patient In cases of this kind the medical practitioner who takes no steps at all is

CIVIL MEDICAL PRACTICE AND THE WAR

To the Editor of THE LANCET

SIR,—The statistics in THE LANCET of Dec 26th last, as given by the President of the General Medical Council, would have been still more interesting if they had shown the percentage of decrease in each class of medical students, and also if they had set out the actual numbers in ordinary times of the excess over those removed by death, &c , which, of course, is sure to be larger this year As Sir Donald MacAlister says the whole question calls for consideration, I may be permitted as an old member of the General Medical Council to make a humble suggestion as to how the deficiency of doctors might for a time at least be met

While I agreed at the time to the addition of a fifth year to the medical curriculum, I and others did so on the clear understanding that the additional year should be devoted *wholly* to clinical—i e , practical—work It is notorious that this has not been so The fifth year as a rule has been appropriated by further study, and comparatively little has been left for taking charge of individual patients as house surgeon's or house physician's clerk, or as *pupil* assistant Wherever we turn the state of war has of necessity altered existing arrangements, and new ways of going to work have had to be considered Not only many medical students but many medical men have gone "to the front" While it is true that in their absence their neighbours have generously looked after their patients, or locum tenents have been found to take their place, I fear at great expense, yet both the patriotic practitioner and the public have suffered from this dearth of doctors This being so for the good of all, and I firmly believe without detriment in the interests of real medical education, a large proportion of fifth year students (including during war hospital internes) might be allowed to act as unqualified assistants for the time being, and afterwards to go up for their final examination before being admitted to the Medical Register on producing a certificate that their time on probation had been conscientiously spent—in other words, that their apprenticeship had been profitably accomplished

If the result of this temporary experiment were found to be satisfactory then the same system might be continued after the war was over, and the coming scarcity of doctors would be met It would be the means of adding, if not quite a fifth year by year at least a tenth to the working army of the profession

I am Sir, yours faithfully,

[illegible] WILLIAM BRUCE M D

P S —Since the foregoing was written I have carefully perused both Sir Donald MacAlister's further letter and the able report of Dr Norman Walker's speech at Glasgow The thanks of the profession for the trouble taken by these gentlemen are most heartily due As regards the new order of the War Office for which we have to thank the President and the Medical Council, will in many cases greatly relieve the situation for the time being, while the action of Dr Walker and his committee is sure to bear good fruit All the same, practically nothing is being done to meet the deficiency in numbers which Dr Walker clearly shows must go on increasing Whereas by shortening the term of academic residence a very considerable addition, as I have said, would be effected to the whole body of medical practitioners were it to include those fully licensed and those in process of being qualified for registration

To the Editor of THE LANCET

SIR,—The prospective diminution of our reserve supply of medical men will perhaps call attention to the question if we are making the best use of the abilities of the men we have already qualified Apart from the Scottish born student, who can if he thinks fit get his training at the expense of the Carnegie Trust, the cost of the curriculum to the English trained student may run to anything from £500 to £1000 After qualifying, if the student has a capital of £1000 to £1500 his course will be plain sailing But what are the restrictions on others who have not this reserve? They are brought up against restrictions of a commercial kind, for the most part framed to protect the business or trading interests of the established practitioner Hence the legal bond not to practise within ten miles of a place where a qualified practitioner may have been compelled from economic circumstances alone to accept a subsidiary position If the qualified practitioner sets up in practice on his own, so to speak, he is again met with the restrictions of the insurance doctors, whose panel patients cannot change their attendant more than once a year, and then only by a very troublesome clerical procedure So that unless the young qualified man can get together some £2500 and spend many years getting his capital back, he may very well think twice before taking up the occupation There is more in the question surely than our academicians can alter or control I am, Sir, yours faithfully,

Burnley, Dec. 28th, 1914 JAMES I HALSTEAD

MAGNESIUM SULPHATE IN TETANUS

To the Editor of THE LANCET

SIR,—In connexion with the great prevalence of tetanus among the wounded soldiers in France and the inefficiency of tetanus antitoxin except as a prophylactic, allow me to call the attention of your readers to the great service of magnesium sulphate administered by hypodermoclysis in from 1 to 2 per cent solution, in quantities and at intervals depending upon the severity of symptoms—a pint to a quart even every three hours if necessary I inclose for your perusal a copy of the notes of two cases I reported some years ago [1]

The effect of this salt in solution, administered intraspinally as an anticonvulsant, is generally well known, but that the same result may be obtained with much greater ease and safety by employing dilute solutions in large amounts hypodermatically is I think not recognised and might I am sure at this juncture prove of great service I venture to urge its trial extensively, especially where established measures have failed

I am Sir yours faithfully,

Brooklyn New York H GILLETT M D

---

[1] [illegible]

whooping cough, which had been 32, 35, and 28 in the three preceding weeks, rose to 44 last week, and included 27 in Glasgow, 6 in Dundee, 4 in Clydebank, 3 in Greenock, and 2 in Motherwell The deaths referred to scarlet fever, which had been 14, 17, and 15 in the three preceding weeks, rose to 17 last week, of which 6 were registered in Glasgow 5 in Aberdeen, and 3 in Paisley The fatal cases of diphtheria, which had been 16, 9, and 16 in the three preceding weeks, fell to 14 last week, and included 4 in Edinburgh, 3 in Glasgow, and 2 each in Aberdeen and Motherwell The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 8 15, and 12 in the three preceding weeks, were 11 last week, of which 4 belonged to Dundee and 3 to Glasgow The 10 deaths referred to measles were 7 above the average in the earlier weeks of the quarter, and included 8 in Dundee The 2 fatal cases of enteric fever were registered in Glasgow

The deaths referred to diseases of the respiratory system, which had been 154, 169 and 175 in the three preceding weeks, further rose to 210 in the week under notice, 42 deaths resulted from various forms of violence, against 36 in each of the two preceding weeks

---

HEALTH OF IRISH TOWNS

In the 27 town districts of Ireland 383 births and 393 deaths were registered during the week ended Saturday, Dec 26th 1914 The annual rate of mortality in these towns, which had steadily increased from 17 7 to 21 8 per 1000 in the six preceding weeks, fell to 17 0 per 1000 in the week under notice During the first 12 weeks of last quarter the mean annual death rate in these towns averaged 18 0, against corresponding rates of 14 4 and 16 5 per 1000 in the English and Scotch towns respectively The annual death rate during the week was equal to 16 4 in Dublin (against 12 8 in London and 19 8 in Glasgow), 22 0 in Belfast, 14 3 in Cork, 11 4 in Londonderry, 13 5 in Limerick, and 9 5 in Waterford, while in the 21 smaller towns the mean death rate was 12 5 per 1000

The 393 deaths from all causes were 110 fewer than the number in the previous week, and included 32 which were referred to the principal epidemic diseases, against 43 and 46 in the two preceding weeks Of these 32 deaths, 9 resulted from measles, 9 from infantile diarrhœal diseases, 5 from whooping-cough, 3 each from scarlet fever, diphtheria, and enteric fever, but not one from small pox. The mean annual death rate from these diseases was equal to 1·4, against corresponding rates of 1 2 and 1 8 per 1000 in the English and Scotch towns respectively The deaths attributed to measles, which had been 8, 12, and 8 in the three preceding weeks, numbered 9, and were all registered in Belfast The deaths of infants (under 2 years) referred to diarrhœa and enteritis, which had been 12, 17, and 15 in the three preceding weeks, fell to 9, of which 5 occurred in Dublin The fatal cases of whooping-cough, which had been 4 3, and 5 in the three preceding weeks, were again 5, and were all recorded in Belfast The deaths attributed to scarlet fever, which had been 8 8, and 10 in the three preceding weeks fell to 3, but showed no excess in any town The 3 deaths referred to enteric fever of which 2 occurred in Dublin and 1 in Sligo were equal to the average in the earlier weeks of the quarter Of the 3 fatal cases of diphtheria, 2 were recorded in Dublin and 1 in Cork

The deaths referred to diseases of the respiratory system, which had been 90, 120, and 105 in the three preceding weeks, further fell to 96 in the week under notice Of the 393 deaths from all causes 97, or 25 per cent, occurred in public institutions, and 9 resulted from various forms of violence The proportion of uncertified causes of death was equal to 4 1 against 1 1 per cent, in the 97 English towns

In the 27 town districts of Ireland with an aggregate population estimated at 1,205,280 persons at the middle of 1914 649 births and 643 deaths were registered during the week ended Saturday, Jan 2nd The annual rate of mortality in these towns, which had been 21 1, 21 8, and 17·0 per 1000 in the three preceding weeks rose to 27 8 per 1000 in the week under notice During the 13 weeks of the quarter just ended the mean annual death rate in these towns averaged 18 8, against corresponding rates of 14·9 and 16 8 per 1000 in the English and Scotch towns respectively The annual death rate last week was equal to 35 2 in Dublin (against 23 7 in London and 23 9 in Glasgow), 23 1 in Belfast, 30 6 in Cork, 22 8 in Londonderry, 28 4 in Limerick, and 51 3 in Waterford, while in the 21 smaller towns the mean rate did not exceed 19 5 per 1000

The 643 deaths from all causes were 250 in excess of the number in the previous week, and included 42 which were referred to the principal epidemic diseases, against 46 and 32 in the two preceding weeks Of these 42 deaths, 10 resulted from infantile diarrhœal diseases 9 each from measles and scarlet fever 7 from whooping cough, 4 from enteric fever and 3 from diphtheria, but not one from ll pox The mean annual death rate from these diseases equal to 1 8, against 1 7 and 2 2 per 1000 in the English and Scotch towns respectively The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 17, 15, and 9 in the three preceding weeks were 10 last week, of which 8 were registered in Dublin The deaths referred to measles which had been 12, 8, and 9 in the three preceding weeks, were again 9 last week, and comprised 8 in Belfast and 1 in Queenstown The fatal cases of scarlet fever, which had been 8, 10, and 3 in the three preceding weeks rose to 9 last week, and included 4 in Waterford and 2 each in Dublin and Belfast The 7 deaths attributed to whooping-cough of which 4 occurred in Dublin and 2 in Belfast were 3 in excess of the average in the earlier weeks of the quarter Of the 4 deaths referred to enteric fever, 2 each were registered in Dublin and Belfast The 3 fatal cases of diphtheria included 2 in Dublin and 1 in Belfast, and were equal to the average in the earlier weeks of the quarter In addition to the above, a death from typhus occurred in Waterford

The deaths referred to diseases of the respiratory system, which had been 120, 105, and 96 in the three preceding weeks, rose to 162 in the week under notice Of the 643 deaths from all causes, 196, or 30 per cent, occurred in public institutions, and 7 resulted from different forms of violence The causes of 37, or 5 8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest, in the 97 English towns the proportion of uncertified causes did not exceed 1 1 per cent

PARIS

(FROM OUR OWN CORRESPONDENT)

The Licence Fees of Mobilised Medical Men

A DELEGATION from the Societe Centrale and from the Association Generale des Medecins de France attended recently at the office of direct taxation at the Ministry of Finance to call attention to the situation of mobilised doctors in regard to their licence fees during the years 1914 and 1915 It was stated in reply to the delegation's representations that it was impossible to make any abatement for 1914, but that mobilised medical men whose usual residence was in Paris would not appear on the register of practitioners for 1915 or during the period of hostilities, and that provincial practitioners should apply to the director of direct taxation of the province for a discharge, which would be favourably considered in every case This measure is indeed only just In Paris, especially, all the medical men have to pay for their licence to practice a heavy fee in proportion to their rent Since, however, during mobilisation their emoluments are entirely inadequate to compensate them for the loss caused by the abandonment of their practice, it is not right that they should be called on to pay the fee for their licence

Hygiene in War Devastated Areas

In the fighting area and in regions under military occupation hygienic knowledge is indispensable When the dispossessed inhabitant returns to his village a great danger arises from the sources of contamination that every battle or the long occupation by troops leaves behind It is necessary, therefore, that all such country should be purified, for the sources of infection are innumerable A deputy from the Ardennes, Dr Doisy, who has returned from a visit to the battle area of the Marne, gave an address on this subject in a conference organised by the Alliance d'Hygiene Sociale He pointed out that the first difficulty encountered by the military sanitary service had consisted in the vastness of modern battlefields, another in the season of the year and the high temperature which still prevailed at the beginning of September This explained why the burials had been conducted in such an inadequate manner, why disinfectants gave out, and why it was now necessary to secure protection against grave dangers This whole region of bloody battlefields must be visited and probed

In sleeplessness due to gastro intestinal restlessness a few drops of peppermint or spirit of camphor or a wineglassful of orange flower water will often exert a quasi hypnotic effect

Whatever the effect of errors of refraction it is certain that insomnia results from many other small causes —I am, Sir, yours faithfully,

the foremost place, and the medical practitioner in charge of a patient will be right in permitting no steps to be taken which are dangerous to her life or detrimental to her condition of health

In cases of abortion where, after consultation with a specialist, it is decided that there is conclusive objective evidence of criminal interference, quite irrespective of any statements made by the patient, then there is no doubt that the duty rests with the medical practitioner to inform the legal authorities His duty to the public and to himself must, I think, in such cases override any obligation of secrecy arising out of the confidential relationship to which a doctor stands towards a patient

Welbeck-street, W, Jan 5th, 1915

INSOMNIA AND SUICIDE

To the Editor of THE LANCET

SIR,—The paper by Mr C E Pronger under the above title in your issue of Dec 12th, 1914, has brought into prominence what some of us have been preaching for years, and it has seemed as if the preaching were in vain The medical profession allows that there is such a thing as eyestrain, and that the correction of errors of refraction may cure headaches, and there many appear to stop, and do not realise that if eyestrain can cause headaches, why not also numerous other forms of reflex irritation or waste of nerve energy—in fact, any "functional" nerve disorder? When some years ago Gould, of Philadelphia, published his "Biographic Clinics" and illustrated the enormous harm that uncorrected astigmatism could do and had done, he was laughed at and called a madman, and yet those who have followed in his footsteps look up to him as a pioneer in ophthalmology second only to the great Donders

If small errors of refraction may play such an important rôle it will be surely asked why the profession generally have not accepted the fact, and the answer is because a large majority of the *oculists* themselves have not done so They laugh at the man who corrects 0 12 D of astigmatism or 0 25 D of anisometropia, and almost infer that he is "next door" to a quack We are so conservative in the medical profession and forget that the only form of conservatism for us is to conserve what is good As soon as one of us opens a new door and ets in a new light it seems as if the whole rofession did their best to close the door instead of helping to open it wider

The explanation of this attitude is not far to seek in the subject under discussion It is that the "older school" have failed to recognise the paramount importance of the use of cycloplegics in this particular work Very low errors of astigmatism or of anisometropia, such as 0 12 D, 0 25 D, 0 37 D, and possibly 0 5 D play the chief rôle in causing nervous disorder in a particular class of nerve patient These low errors, and only these low errors, can be corrected unconsciously by the patient, and are only fully revealed when a cycloplegic is used in all under 45 (and in some cases 50) years of age Homatropine generally suffices for the older patients, but atropine must be used for all up to the age of 25 or even 30 The masking of the defect enables the patient to have apparently normal vision, and he is totally unconscious of, and very often indignant at the mere suggestion of, ective vision. This unconscious correction of small errors must always lead to waste of nerve energy, but in the robust it may never manifest itself, or the manifestation may be long delayed, but in those whose nervous organisation is of a more delicate character it very soon shows itself in some form of functional nerve disorder—insomnia, depression, suicide, drug taking, alcoholism, dyspepsia, &c

Having found the defect—and in doing this the ophthalmometer is a priceless servant—the logical treatment is the prescription of the correction for constant use, and herein we perform a double good, for not only do we remove the symptoms, but also the cause, for in the younger patients the removal of the eyestrain tends to the disappearance of the error I have heard it said that most of the cures are the result of "suggestion", it is possible that an occasional case does occur of such a class, but suppose suggestion were the cure in all, is that an argument against the treatment? Is not our one and only aim to cure the patient? It should be remembered that the cases referred to above only occur very sparsely in hospital work, they must be looked for in the upper classes, especially in the professional classes Some of the most typical cases I have seen have been members of our own profession Women at the climacteric are especially prone to this form of eyestrain, the oncoming presbyopia added to the static error increasing the trouble or starting it The opticians' art has rendered a lasting benefit by inventing the invisible bifocal glass, wherein the upper portion corrects the static error and the lower portion the same, plus the presbyopia

If the good that men do in this world is gauged by the benefits it confers on the race then the oculist who does his refraction work sensibly and carefully must have the consciousness of being a large benefactor —I am, Sir, yours faithfully,

Chandos-street, W, Jan 1st 1915

ERNEST CLARKE

To the Editor of THE LANCET

SIR,—If it be true, as suggested by Mr C Ernest Pronger in THE LANCET of Dec 12th, 1914, that errors of refraction play a part in the production of habitual insomnia, it only affords another proof of the fact that this distressing condition is often dependent upon trifling disturbances of physiological equilibrium Nothing, for instance, is more fatal to a good night's rest than going to bed with a loaded rectum, especially in presence of a tendency to flatulence, because this tends to excite peristalsis and wakefulness A glycerine suppository or injection under these conditions will exert distinctly hypnotic effects An empty stomach is also adverse to sleep and should be combated by a biscuit or a cup of warm milk on retiring, these being far more efficacious than the customary alcoholic nightcap Then, too, there is the question of having the head high or low, which is a matter of personal idiosyncrasy A cold bedroom is more conducive to sleep than one artificially heated, and free ventilation, provided no cold air impinge directly on the exposed surfaces, is favourable to deep, refreshing sleep The use of a feather bed or unduly thick, heavy bedclothes, by overheating the body, produces restlessness, and in elderly men is apt to cause bladder irritability, with consequent disturbance of rest Another frequent cause of troubled nights is the practice of taking a heavy meal late in the day with too short an interval between the meal and the hour

In sleeplessness due to gastro intestinal restlessness a few drops of peppermint or spirit of camphor or a wineglassful of orange flower water will often exert a quasi hypnotic effect

Whatever the effect of errors of refraction it is certain that insomnia results from many other small causes —I am, Sir, yours faithfully,

INSOMNIA AND SUICIDE

To the Editor of THE LANCET

SIR,—The paper by Mr C E Pronger under the above title in your issue of Dec 12th, 1914, has brought into prominence what some of us have been preaching for years, and it has seemed as if the preaching were in vain The medical profession allows that there is such a thing as eyestrain, and that the correction of errors of refraction may cure headaches, and there many appear to stop, and do not realise that if eyestrain can cause headaches, why not also numerous other forms of reflex irritation or waste of nerve energy—in fact, any "functional" nerve disorder? When some years ago Gould, of Philadelphia, published his "Biographic Clinics" and illustrated the enormous harm that uncorrected astigmatism could do and had done, he was laughed at and called a madman, and yet those who have followed in his footsteps look up to him as a pioneer in ophthalmology second only to the great Donders

If small errors of refraction may play such an important role it will be surely asked why the profession generally have not accepted the fact, and the answer is because a large majority of the oculists themselves have not done so They laugh at the man who corrects 0 12 D of astigmatism or 0 25 D of anisometropia, and almost infer that he is "next door" to a quack We are so conservative in the medical profession and forget that the only form of conservatism for us is to conserve what is good As soon as one of us opens a new door and lets in a new light it seems as if the whole profession did their best to close the door instead of helping to open it wider

The explanation of this attitude is not far to seek in the subject under discussion It is that the "older school" have failed to recognise the paramount importance of the use of cycloplegics in this particular work Very low errors of astigmatism or of anisometropia, such as 0 12 D , 0 25 D , 0 37 D , and possibly 0 5 D play the chief rôle in causing nervous disorder in a particular class of nerve patient These low errors, and only these low errors, can be corrected unconsciously by the patient, and are only fully revealed when a cycloplegic is used in all under 45 (and in some cases 50) years of age Homatropine generally suffices for the older patients, but atropine must be used for all up to the age of 25 or even 30 The masking of the defect enables the patient to have apparently normal vision, and he is totally unconscious of, and very often indignant at the mere suggestion of, defective vision This unconscious correction of small errors must always lead to waste of nerve energy, but in the robust it may never manifest itself, or the manifestation may be long delayed, but in those whose nervous organisation is of a more delicate character it very soon shows itself in some form of functional nerve disorder—insomnia, depression, suicide, drug taking, alcoholism, dyspepsia, &c

Having found the defect—and in doing this the ophthalmometer is a priceless servant—the logical treatment is the prescription of the correction for constant use, and herein we perform a double good, for not only do we remove the symptoms, but also the cause, for in the younger patients the removal of the eyestrain tends to the disappearance of the error I have heard it said that most of the cures are the result of "suggestion", it is possible that an occasional case does occur of such a class, but suppose suggestion were the cure in all, is that an argument against the treatment? Is not our one and only aim to cure the patient? It should be remembered that the cases referred to above only occur very sparsely in hospital work, they must be looked for in the upper classes, especially in the professional classes Some of the most typical cases I have seen have been members of our own profession Women at the climacteric are especially prone to this form of eyestrain, the oncoming presbyopia added to the static error increasing the trouble or starting it The opticians' art has rendered a lasting benefit by inventing the invisible bifocal glass, wherein the upper portion corrects the static error and the lower portion the same, plus the presbyopia

If the good that men do in this world is gauged by the benefits it confers on the race then the oculist who does his refraction work sensibly and carefully must have the consciousness of being a large benefactor —I am, Sir, yours faithfully,

Chandos-street, W , Jan 1st 1915 ERNEST CLARKE

To the Editor of THE LANCET

SIR,—If it be true, as suggested by Mr C Ernest Pronger in THE LANCET of Dec 12th, 1914, that errors of refraction play a part in the production of habitual insomnia, it only affords another proof of the fact that this distressing condition is often dependent upon trifling disturbances of physiological equilibrium Nothing, for instance, is more fatal to a good night's rest than going to bed with a loaded rectum, especially in presence of a tendency to flatulence, because this tends to excite peristalsis and wakefulness A glycerine suppository or injection under these conditions will exert distinctly hypnotic effects An empty stomach is also adverse to sleep and should be combated by a biscuit or a cup of warm milk on retiring, these being far more efficacious than the customary alcoholic nightcap Then, too, there is the question of having the head high or low, which is a matter of personal idiosyncrasy A cold bedroom is more conducive to sleep than one artificially heated, and free ventilation, provided no cold air impinge directly on the exposed surfaces, is favourable to deep, refreshing sleep The use of a feather bed or unduly thick, heavy bedclothes, by overheating the body, produces restlessness, and in elderly men is apt to cause bladder irritability, with consequent disturbance of rest Another frequent cause of troubled nights is the practice of taking a heavy meal late in the day with too short an interval between the meal and the hour for retiring to rest in evidence to impair their usefulness as railway servants and to reject them. I can recall no instance in which a man rejected for a nervous stammer was also found to be red green blind During the past three years I have carefully watched for such a combination There is a complete record of all cases examined in this office In one case only was a man rejected for defective colour sense who also had a nervous stammer He was normal by Holmgren's wools, but he named pale green white in the lantern Unfortunately at that time I had no knowledge of the value of either Stilling's or Nagel's test and therefore cannot state the real value of his colour defect From this evidence it is at least probable that a nervous stammer is much rarer in colour blind persons than in colour normal persons

I am, Sir, yours faithfully,

GEORGE HENRY TAYLOR,
Railway Medical Officer

THE ABUSE OF TEA.

To the Editor of THE LANCET

SIR,—While conducting investigations into the dietary of the labouring classes I have been most forcibly impressed by the injurious effects of excessive tea drinking amongst them Tea is the invariable accompaniment of every meal, and as though this were not sufficient it is frequently drunk between meals The effects of this over indulgence, though noticeable on all sides, are particularly pronounced in the case of nursing and expectant mothers the general disturbance of nutrition, in addition to local digestive troubles, being accentuated in them I feel sure that the abuse of tea is one of the most potent causes of the inability of the women to suckle their babies, and is thus an indirect cause of a high infantile mortality In Birmingham during the hot weather 30 times more bottle fed babies die than those breast-fed, and among the survivors the bottle fed are at a great disadvantage as compared with the naturally fed babies In my work at Birmingham I have therefore sought to find a substitute for tea. It is of no use to counsel moderation and advance the virtue of plain water, the poor refuse to consider such a change Cocoa, however, has proved in practice an acceptable alternative to them and I am satisfied as to the good results which accrue to the mother and the *children* when cocoa is substituted for tea as the family beverage It seems to me that the present is a favourable time for urging a general reform in *this direction*—first, because the price of tea has increased beyond that of cocoa, and secondly, because the people are now more open to receive and *follow advice* with regard to their food I should be much obliged if you could give publicity to this matter, which, though it may appear trivial, is, I am *convinced*, of national importance I am, Sir, yours faithfully,

Birmingham Dec 29th 1914 A E CARVER, M D

TENDIMUS HUC OMNES

To the Editor of THE LANCET

SIR —We are all aware that 'to every man upon this earth death cometh soon or late, but the usual impression is that the man whose profession is fighting runs a greater ris[illegible] and when he enters on a campaign, that his chances of escaping from "[illegible] decay" are appreciably increased An American statistician has, however, stated that "ominous as are the soldier's dangers in war, they are really but little greater than are the civilian's dangers of dying before he has time to set aside the necessary nest egg for his dependents" By comparing the statistics of the four considerable wars of the last 50 years—namely, the American Civil War, the Franco German War, the South African War, and the Russo Japanese War of 1904–05—he finds that the average *mortality from all* causes, including the killed in battle and the deaths from wounds and disease, amounted to 90 1 per 1000 per annum in the Civil War it was yet higher, in the South African War it was *only* 40·2 The deaths from disease were practically double those from wounds in the Civil War (66 compared with 32 5) and in the South African War (26 compared with 14 3), the proportions were reversed in the Franco German War (28 8 and 67 7) and in the Japanese War (25 1 and 54 2) Mr E. B Phelps, editor of the *American Underwriter*, of New York, whose figures I am quoting, calculates that if the present war continues for a full year, the number of men engaged amounting to five, or possibly six, millions, it will cost more lives than all causes will demand among the entire adult male population of the United States But he then says that, as a matter of experience, the chances of even the youngest man of marriageable age living long enough to set aside the most modest competence for his family when he is gone are not much better than are the soldier's chances in time of war, instancing, as an example, that whereas out of 92,637 young men, aged 20, engaged in war 84,290 might be expected to be alive at the end of a year's fighting, out of the same number of men of that age engaged in ordinary occupations not more than 84,000 would survive to 32 years of age By a similar comparison he finds that the fighting soldier's chance is better than that of a civilian of 30 surviving to 41, of 40 surviving to 49, or of 50 to 56 These figures are rather startling, and would indicate that the soldier's dangers in war are really but little greater (and in some cases actually less) than are the civilian's chances of dying before he has time to set aside the necessary provision for those dependent on him The bearing of this observation lies in the application of it, which is, of course, that everyone should insure his life, and that the earlier he begins the better bargain he will make I am, Sir, yours faithfully,

VACCINES AND THE GERMAN RAID A USEFUL ANALOGY

To the Editor of The Lancet

Sir,—Dr F C Eve's letter in The Lancet of Jan 2nd shows in *picturesque* language the closeness of the analogy between *the effect of a* vaccine on the resisting power of a patient and the effect of a raid *on the* resisting power *of this* country I suppose that all *of us* who have been busy inoculating soldiers and nurses against typhoid since the war *began* have been making daily use of this illustration When the patient asks what *is the vaccine* expected to do, *one can invite him* to consider the effect of a German raid on our east *coast in times of* peace, drawing a picture of the bustle at the War Office, the activity of the local authorities, *the movement of troops by* road and rail, and above all the prompt enlistment of recruits So far we are agreed *that the illustration is a* very useful one, it is when it is stretched to provide arguments against inoculating in a general infection that I think it ceases to fit the facts In a systemic infection the body is *not* necessarily "swamped with *toxins*," *but*, at any rate in the commencement, is semi poisoned with toxins or bacterial substances scattered throughout it The parallel is the case of England permeated with spies and potential enemies, *citizens of a* foreign power Dr Eve assumes that in such a condition of systemic infection all the defences are thoroughly aroused We know that this is not true in the case of England, I believe that it is not necessarily true in the case of the body Both are lethargic, neither *may* have mobilised their full resources though the danger is urgent The reason in both cases is, I think, that the danger though urgent is diffuse Nowhere is it concentrated, nowhere is it sufficient to stimulate the locality into resistance In such a case the east coast raid (or an inoculation) would *provoke* a powerful local stimulus, and this may break down the lethargy and help to stimulate defence against the hidden danger within The more the country is permeated with *enemies, or* the more the body is permeated with bacterial substances, the greater is *the difficulty* or danger of stimulating a local production of protective powers, yet such protective powers must be produced or the body will die

Of course, in the extreme case supposed by Dr Eve, all the country being "swamped with toxin" (i e, a million or more *German soldiers* being in full possession of the country), the human body, or the body *politic*, would be moribund, and any inoculation would be far too late These analogies can only serve to illustrate one's point of view, they can never provide arguments for that point of view

I am, Sir, yours faithfully

WHAT IS STRUMA?

To the Editor of The Lancet

Sir,—Virchow once described "struma" as an "abnormal vulnerability of the tissues," a definition, be it observed, which does not imply any connexion with tuberculosis Accepting, then, for argument's sake this definition as correct, the logical inference is that strumous looking persons are merely those whose tissues *form* an admirable cultivation medium for many pathogenic organisms, but most of all for the tubercle bacillus The latter, being the most ubiquitous, has possibly the best opportunity for infecting the favourable soil, and thus *it may be* that strumous looking persons actually become the *subjects of* tuberculosis for the reason that their tissues happen to offer the least resistance to the cultivation attempts of this particular bacillus. Meanwhile, the strumous looking person is one whose "abnormal vulnerability" *depends* upon hypothyroidism, the signs of which cease under thyroid treatment

TWO UNLOOKED FOR EFFECTS OF DRUG EXCRETION

To the Editor of The Lancet

Sir,—The two following cases came to my notice while acting as medical officer of a submarine cable company Before describing them I must say a word about the structure of a cable In the middle is a core of copper wire surrounded by a layer of guttapercha insulation This in turn is surrounded by a layer of brass tape spirally wound, and outside of this a layer of hemp and one of galvanised steel wires, the whole being surrounded by an outermost coat of guttapercha composition Now in repairing a "fault" it is necessary to cut out the fault and joint a new piece in The jointing is done by special men and is a business requiring considerable skill and practice The most important parts of the job are the soldering of the copper core and the efficient application of the insulating guttapercha The jointers put this on hot *and a little at a* time, *forming* layer upon layer, and as each layer is rubbed on they make use of their saliva to rub it smooth and to make it fix in with or adhere to the one before

I can tell now of my two cases One was a jointer who was under treatment for syphilis and was saturated with mercury, and the other was suffering from gonorrhœa and had treated himself lavishly with "santal midi" capsules In both cases the joints made by these men broke down—a somewhat serious matter when you come to consider the cost of submarine cable repairing The reason I can only speculate on, doubtless some of your readers can explain it better than I can My theory is this *that in the* mercurial case there was sufficient mercury excreted in the saliva to make the insulation a partial conductor, in the other case, that the oil in the saliva kept the layers of gutta percha from binding together, for when the joints made by this man were reopened the insulation could be peeled off in thin flakes Both cases are, I think, sufficiently interesting to merit a *record*—I am, Sir, yours faithfully,

Obituary.

THOMAS BRYANT, F R C S ENG, HON M CH R U I, HON M D DUB, HON F.R C S IREL,

CONSULTING SURGEON TO GUY'S HOSPITAL LATE SURGEON IN ORDINARY TO THE KING

THE death of Mr Thomas Bryant, which took place on Dec 30th at his residence, 21 FitzGeorge avenue, Kensington, deprives the profession of a prominent figure in Victorian surgery

Thomas Bryant, who was the eldest son of the late Mr Thomas Egerton Bryant, M R C S, an intimate friend of Sir Astley Cooper, was born in Kennington on May 26th, 1828, and had therefore reached the age of 86 at the time of his death He received his education at King's College School, and in 1846 entered Guy's Hospital as a student, remaining connected with it for the whole of his professional life and being one of its consulting surgeons at the time of his death He qualified as M R C S in 1849 He took the Fellowship of the Royal College of Surgeons by examination on May 12th, 1853, with Mr Richard Barwell, and was therefore one of the two oldest surviving Fellows of the College In 1857 Thomas Bryant was appointed assistant surgeon to Guy's Hospital and in 1859 lecturer on operative surgery On the full staff of the hospital at that time were Gull, Hilton, and Cock, while Wilks was the junior assistant physician, corresponding to Bryant on the surgical side He became full surgeon in 1871 and lecturer on surgery in 1875 He relinquished these posts in 1888 and became consulting surgeon, continuing, however, to give lectures on clinical surgery for a while During his active connexion with Guy's Hospital he was simultaneously carrying on a very large private practice as an operating and consulting surgeon—indeed, during what may be called the immediate pre Listerian period he was one of the leading surgeons in the metropolis, and fully deserved the position

Thomas Bryant

Mr Bryant's connexion with the Royal College of Surgeons of England was an exceedingly long one He became a member of the Council in 1880, at the same time as Lister, whom he just beat in the voting While on the Council he filled with efficiency every available appointment He was a member of the Court of Examiners from 1882 to 1892, as well as a representative of that court on the Board of Examiners in Dental Surgery in 1887 In 1888 he was Hunterian professor of surgery and in 1889 Bradshaw lecturer of the College In 1890 he was elected President, and in 1891 he became the representative of the College on the General Medical Council In 1893 he was Hunterian orator He was President of the College for three years, but in this position made no particular mark, for his business aptitude was not great His handsome presence, urbanity, and real kindness of heart were his chief assets in public life Bryant was for many years—namely, from 1891 to 1904—the representative of the Royal College of Surgeons of England on the General Medical Council, and for part of this time he acted as honorary treasurer He was a pleasant colleague on the Council, and had a very high standard of professional ethics, but he was treasurer at a difficult period in the finances of the Council, and his designs for meeting the position did not escape criticism He also occupied the presidential chair of various professional societies, the Medical Society of London in 1872 the Hunterian Society in 1873, the Clinical Society in 1885, and the Royal Medical and Chirurgical Society in 1898–99

N B —This list, published for the convenience of candidates is issued subject to its approval by the Senate

Royal Medical Benevolent Fund —At the last meeting of the committee 29 cases were considered and grants amounting to £237 were voted to 25 of the applicants The following is a summary of the cases relieved —

Widow aged 74 of M.R C S Eng who practised at Braintree Husband died 23 years ago and left her without means She has managed to support herself but unable to save until incapacitated by old age Lives with married son who has three children and only a small salary Voted £2 and referred to the Guild.—M.R.C S Eng and L.R C P Lond, aged 48 who practised in Lancashire Has become blind Married two children Wife and children live with relatives Wants a little help to obtain some training in massage Voted £10 and referred to the Guild —Widow aged 66 of L.S A. Lond who practised at Bournemouth At her husband s death in 1913 was left without any income and unable to obtain suitable employment. Only income 10s per week from the Society of Apothecaries Voted £12 in six instalments and referred to the Guild — Daughter aged 45 of M D Edin who practised at Southampton. Trained as a midwife but recently had to undergo a serious operation and has been ten weeks in bed Voted £10 in two instalments and referred to the Guild —Daughter aged 40 of M D St. And who practised at Swinton Lancs Was a teacher but underwent a severe operation in September 1913, and has not been able to work since. Mother has only a small annuity and has to keep an invalid son Voted £18 in 12 instalments —Daughter aged 68 of M.R C S Eng who practised in London Has been a teacher for 40 years in England Russia and Germany On account of the war had to return from Moscow four months ago where she had been in one post for seven years All her savings were in the Deutsche Bank, Berlin and could not obtain any Voted £12 in 12 instalments and referred to Guild —Widow aged 66 of M.R.C S Eng who practised at Heywood Lancs Has endeavoured to earn a living by acting as housekeeper and cook but owing to age and the war finds it impossible at present to obtain a suitable post Voted £2 and referred to the Guild.—Daughter aged 74 of M R C S Eng who practised in London Up to quite recently has acted as a church visitor at £35 per annum but owing to age has had to give it up Has a small pension from the Mercers Company Voted £12 in 12 instalments —Daughter aged 47, of M D St And who is too old to practise and too poor to help Earned her living as a teacher until three months ago when owing to internal trouble had to enter a nursing home and now all her savings are gone Voted £5 and arrangements to be made to have the applicant operated upon.—Widow, aged 40 of M R.C S Eng and L R C P Lond who practised at Norwood Husband died quite suddenly from typhoid leaving the applicant and three young children in straitened circumstances Voted £5 —Daughter aged 50 of M R C S Eng who practised at St Clears Has double curvature of the spine Lives with mother who is a pensioner of the Fund and two delicate brothers who *cannot afford to* keep her Relieved once £6 Voted £6 in 12 instalments.—Widow aged 41 of M R C S Eng who practised in N Wales Has two young children. Endeavours to earn a living by selling clothes on commission but owing to the war the sales have greatly diminished Relieved three times £30 Voted £10 in two instalments —Widow aged 60 of L.R C P & S Edin who practised in London Present distress caused by death of only son who supported her Earns a little by needlework. One daughter allows her 5s per week otherwise no other support Relieved twice £20 Voted £10 in two instalments —Daughter aged 56 of L.R C P Lond who practised at Hammersmith Unable to work through ill health Only income a little from the Guild and occasional gifts of food and clothing Relieved seven times £36. Voted £18 in 12 instalments.—Widow aged 69 of M R C S Eng who practised in Ireland and America. Suffers from muscular rheumatism One son who has not been heard of for a long time No income and unable to work Relieved five times £50 Voted £12 in 12 instalments —Daughter aged 68 of M D Edin who practised at Cheltenham Eyesight very bad and ill health prevents her doing any work Only income £13 10s per annum and a little from friends Relieved once £12. Voted £12 in 12 instalments —Widow aged 63 of M R C S Eng who practised at Yelverton Takes paying guests but owing to the bad season is in difficulties. Relieved five times £52. Voted £12 in 12 instalments —Daughter aged 58 of L.R C P Lond and L.S A. Lond who practised at Brierley Hill Health very bad and unable to do any permanent work Income a R.U K B Assoc. pension of £21 per annum and from frie[illegible] month Relieved seven times £41 Voted £12 in 12 instalments — Daughter, aged 52, of M R.C S Eng who practised in London Has had several internal operations and obliged to mortgage her small capital to pay for same Lives with married sister who gives her a home but unable to keep her Relieved five times £54 Voted £10 in two instalments —Daughter aged 63 years of M R C S Eng. who practised at Northampton Health very indifferent Has a small annuity but not sufficient to live on Relieved once, £5. Voted £5 — Daughter aged 47 of M R C S Eng who practised in India. Is bedridden and quite helpless Only income an annuity from the British Home for Incurables Relieved three times £36. Voted £12 in 12 instalments —Widow aged 43 of M D Irel who practised at Newcastle-on Tyne Health indifferent, but endeavours to make a little by taking lodgers Allowed £25 per annum for education of only child Relieved four times £30 Voted £. — Daughter aged 48 of M R C S Eng who practised at Gillingham. Has very indifferent health and unable to find suitable employment Recently has been selling papers in the streets at a remuneration only sufficient to pay the rent of a room Relieved once £5 Voted £12 in 12 instalments and referred to the Guild —Widow aged 56, o L.S A. Lond who practised at Limehouse Endeavours to make a living by letting rooms but not very successfully Two daughters who are in service can only allow her 5s per month Health bad. Relieved nine times £46 Voted £12 in 12 instalments —Daughter aged 66, of M R C S Eng who practised at Great Torrington Has acted as housekeeper and general help, but at present out of employment *as her age is against her* Relieved *once* £12. Voted £1 and referred to the Guild for report

In addition to the above the committee appointed from the grantees six annuitants at £20 each This brings the total of annuitants up to 142 Contributions may be sent to the honorary treasurer Dr S West 11, Chandos street Cavendish square, London W

Royal College of Surgeons in Ireland —At a meeting of the College held last week Professor Edward H Taylor was unanimously elected to the place on the council vacant by the death of Mr F T P Newell.

Anthrax and its Notification —An adjourned inquiry was concluded on Jan 4th by Dr F J Waldo, at the Southwark coroner s court into the death of a butcher s manager named Tarrant, aged 46, who died in Guy's Hospital from anthrax. It was stated that Tarrant's employer purchased his meat from a firm whose head slaughterman died from anthrax at Croydon, and about the same time the deceased complained of a pustule on his neck which was diagnosed as anthrax A clerk of the same wholesale firm and a son of Tarrant s employer were also suffering from the same disease, but were recovering and another man had since contracted the disease and a horse had died from it Dr T M Legge, H M Inspector of Factories and Workshops, in the course of his evidence, stated that anthrax was a notifiable disease when occurring in a factory, but a butcher s premises were not technically a factory He had never heard of anthrax being communicated by frozen rabbits The coroner read a letter from the High Commissioner for New Zealand informing him that there had not been a case of anthrax in that country for years, and that frozen rabbits had never been known to carry the infection Dr Legge further stated that in some districts registrars of deaths reported deaths from anthrax to the chief factory inspector, which was very useful and in his opinion the disease should be compulsorily notifiable to coroners in fatal cases Evidence on behalf of the wholesale firm showed that great care was taken in the purchase of cattle, and that since the present cases their premises had been thoroughly disinfected Dr R V Clarke, medical officer of health of Croydon, said that every possible assistance had been given him by this firm, who had supplied a complete list of all animals they had dealt with and their sources He agreed that it would be very useful if all deaths from anthrax were reported to the coroner He had never seen anthrax in frozen meat The city coroner in the course of his summing up, said that he had always advocated the addition of anthrax to the list of infectious diseases compulsorily notifiable to the medical officer of health The Guy s Hospital authorities always notified fatal cases of anthrax to him. It seemed strange that whereas all cases of anthrax in the human subject were not compulsorily notifiable, all cases in the lower animals were compulsorily notifiable under the stringent regulations of the Contagious Diseases (Animals) Act The jury returned a verdict of "Death from anthrax" but added that there was not sufficient evidence to show how it was contracted, the verdict amounting thus to one of "Death from misadventure" In a rider they suggested that all doctors attending such cases should be compelled to notify to the medical officer of health and that all deaths should be compulsorily reported to the coroner This recommendation will be forwarded by the coroner to the Local Government Board and other authorities practically certain to ensue, yet he never shirked responsibility, though I know with what extreme anxiety he always approached these cases and how keenly he felt failure when it occurred

Bryant's position in regard to Listerism was peculiar, he never could bring himself to adopt it, and he was one of the two leading surgeons who spoke for the 'opposition' at the conclave held—early, I think, in the 'seventies'—at St Thomas's Hospital to consider the merits of this method as then evolved He spoke against it in an unqualified manner, but to this, I think, he was prompted by the success undoubtedly enjoyed by the general methods of cleanliness that he had so long practised and to which he thought little could be added by way of improvement And at that time it must be remembered that carbolic acid was rather a two edged tool to play with, for it was far from pure, causing intense irritation, not only to the operator, but to the patient, and that to a degree unsuspected by those who now have only to deal with the absolutely pure chemical He necessarily also never made use of the 'spray,' though he could not in the nature of things withhold from being gradually influenced by what was developing around him, so the various antiseptic Listerian dressings were by degrees adopted, at least in his hospital practice Having never adopted the antiseptic methods in their entirety, his immediate results were presently not so favourable as those of his colleagues, such as Howse or Davies Colley, who were antiseptic to their finger ends Later on he almost entirely dropped carbolic acid, employing peroxide of hydrogen and iodine water (i e, water with a little tinct iodi added) both in his operations and for the cleansing of foul cavities This is the more interesting to note now, since these two drugs have sprung into notoriety, but my own experience of them in Bryant's practice, which I not only witnessed but which at times I was asked to take charge of, failed to inspire me with confidence in their efficacy, whatever value an immediate compress of tinct iodi on a recent wound may have, for in this way I never knew him to employ the drug

As an ovariotomist, too, Bryant had a great reputation, and he undoubtedly scored many a success in his earlier operations by a scrupulous attention to general details and to cleanliness, as well as to his habit of refraining from all meddlesome handling of organs His success here was markedly increased when he began to employ the extra abdominal method of treating the pedicle by clamping—a practice that, I believe, he was the first to employ in Guy's Hospital, and which was followed for many years There can be no doubt that his scope of work was largely limited in his later years by his never having fully adopted antiseptic methods—for aseptic methods do not apply to his time—and from conversations I have had with him I am convinced he was far too conscientious a man to undertake some of the more modern operations, from a feeling that he was handicapped by not being able to give his patient the full benefit of recent scientific knowledge If Bryant prided himself more on one thing than another it was in being a conservative surgeon and he constantly instilled into his pupils the doctrine that it was wrong, if not immoral, to remove an atom more of the human body than the actual disease warranted Doubtless this, broadly speaking was a good principle to inculcate, but carried too far, as it sometimes was especially in amputations, it led in his practice to some awkward and inconvenient results His teaching, however, in regard to the relationship between surgeon and patient had always an under current of high ideal and straightforwardness Bryant always thought more of his patient than of himself, and I never knew him to be influenced by the desire to improve his statistics—much as he liked these figures—to the extent of either unnecessarily operating or in any way adding to his patient's risk or discomfort

A handsome man, of commanding presence, with a personality that impressed itself on others, genial, kindly, and always ready to lend an ear to any that sought his advice, Bryant was the friend of all who knew him, whether student, colleague, or patient The student felt that in him he had a friend to whom he could go for advice at all times, and never fail to get his sympathy and help To his dressers' mistakes he was lenient, and whilst he never overlooked anything nor hesitated to correct, he at the same time explained and instructed so as to avoid a repetition of a similar mischance As a colleague he was valued by all, and though "once upon a time" there arose a serious difference between himself and a colleague that even threatened the peace of the hospital, he met his quondam friend in the open court of the operating theatre at the instance of their other colleagues, and both men publicly shook hands and thus closed the incident for ever Beyond this nothing ever happened to disturb the harmony with which Bryant performed his public duties at Guy's Hospital, and those who knew him personally will always cherish the memory of him as of a true friend, a courteous gentleman, and if not exactly a pioneer, at any rate a splendid example of the British surgeon

Dr Frederick Taylor writes —"It would be presumptuous in me to say much about Mr Bryant's special qualifications as a surgeon, but I may be allowed to give my impressions of him as a teacher in the school of Guy's Hospital and as a colleague on the medical staff In the middle 'sixties' the surgical teachers most followed by the students at Guy's Hospital were among the surgeons Mr John Hilton, and among the assistant surgeons Mr Thomas Bryant Mr Bryant was then approaching 40 years of age, was tall, upright, handsome, with an easy confident carriage, a cheerful look, and a clear pleasant voice—altogether a very taking personality, with every appearance of knowing exactly what he was about, and without anything that could be fairly regarded as undue self satisfaction He attracted the student by his friendly manner of dealing with his dressers and clerks, and I may also say with his hospital patients Happily these surface markings, so to say, were not belied by anything that he gave us as a surgeon and teacher of surgery In the latter capacity he was highly successful Whether in the out patient room, at the bedside, or in the lecture theatre he always had a large class, and with his clear, incisive speech and the clever arrangement of his facts and arguments he kept the attention of his audience to the last moment of the allotted time At the bedside and in the out patient room he interested himself in the progress of every student even the most junior, and developed to the full the excellent system of teaching by question and answer

As a surgeon he was keen and courageous to a degree He was one of the early successful operators for ovariotomy, and he had the courage to remove

In 1872 he published the first edition of his "Practice of Surgery," which reached a fourth edition in 1884. The book attracted immediate attention from its original features. The illustrations were for the most part original, instead of the old stock illustrations which had for years been reproduced *ad nauseam*; secondly, Bryant introduced the principle of colouring arteries and veins respectively red and blue, and thirdly, he quoted his references to previous authors in place of paraphrasing them with or even without acknowledgment, as was then too commonly the practice. The book was at once recognised as essentially the fruit of experience by a well-practised surgeon, but it was not written upon any plan which enabled it to be kept in the front by new editions as a standard work. It dated from the pre-Listerian era, was an admirable manual, and sold largely, but could not be modernised as surgery progressed. He also published works on "Diseases of the Breast" (1887) on the "Surgical Diseases of Children" (1893), and on "Villous Growths and Common Diseases of the Rectum" (1899), and was a frequent contributor to THE LANCET.

Among the honours that fell to him, he was Sergeant Surgeon to the late Queen Victoria and Surgeon in Ordinary to King Edward VII. Academically he was honoured in 1887 by the Royal University in Ireland with its honorary M.Ch. degree, and in 1892 the University of Dublin gave him its honorary M.D., while the Royal College of Surgeons in Ireland conferred on him its honorary Fellowship.

At the time of his death Mr. Bryant had for some years retired from practice, and it is an open secret that his connexion with certain disastrous financial undertakings left him in very modest circumstances.

Mr. C. H. Golding Bird writes:—"With the death of Thomas Bryant, a representative surgeon and teacher of his day, a link between past and present surgical practice and a man of noble presence has passed away. It was in the late 'sixties' that I first knew him, when he was assistant surgeon to Guy's Hospital, and to his careful, thorough, and lucid teaching many, like myself, owe the foundation of their surgical knowledge. His out-patient day was always crowded, and that not only by students but often by practitioners, whilst his firm yet kindly manner and his sympathetic treatment of the poor attracted the patients themselves, and his name was a household word amongst the dwellers in South London. Always optimistic, contact with him helped the young student along the difficult paths of surgical practice, and even where his hopeful prognostications were seen not to be fulfilled his pupils seemed instinctively to feel that it was no fault of his; for if it—whatever it was—had been possible to any, Bryant was the man to have done it; if he failed, no one else could have achieved it. He was the man to trust. Method, precision, and clear expression in teaching were the keynotes of his success; he would come, always very punctually, to the hospital armed with several note-books, and almost every patient was therein entered with the diagnosis and remarks on the case; and it was from these books he largely drew the statistics for which he had a great liking, but on which I certainly cannot but think an exaggerated value was often placed and from which deductions not always safe were drawn.

The year after his appointment as full surgeon to the hospital his text-book of surgery appeared and was at once welcomed as the best and most up-to-date work for the student. Written rather from the author's clinical experience than from reference to that of others, the book possessed an individuality of its own, and inspired a confidence in what it taught.

A general hospital surgeon in the full sense of the word, Bryant had little sympathy with specialists and specialisms; but in his palmy days research had not differentiated the various departments of surgery as it has done in later years. He, however, was considered by some as a specialist in at least two subjects—viz., the surgery of the breast and the abdomen, particularly in colotomy and ovariotomy. In breast surgery he had been preceded by John Birkett, whose practice, which I knew well, undoubtedly influenced his successor, and though both surgeons only operated in the limited way of their period, the immediate results obtained by Bryant were clinically very remarkable. Strict cleanliness, though only that of soap and water and clean towels, together with rapidity in operating and the important recognition of the harm resulting from the retention of blood and serum in the wound, were his main elements of success. His dressing of a breast case, after the suturing of the wound, consisted in the application for some minutes of firm pressure to express all fluid, and then of a towel, folded as it came from the laundry, over each flap—with generally Friar's balsam on the wound itself—followed by very firm bandaging to prevent the possibility of any re-accumulation of blood. I can vouch for it that Bryant had rarely any complication follow which was directly due to the operation or to the immediate after-treatment, and primary union was not infrequently secured. With the same methods the same success followed his amputations of the breast—a common enough operation at that time. Bryant was most anxious to avoid the use of buried ligatures, which for some time consisted only of silk dipped in boiling wax and carbolic acid, so when torsion was found feasible he became its pioneer at his hospital, and the forceps for the purpose used for many years, and which preceded Spencer Wells forceps, were, I believe, of his own pattern—at any rate, they always bore his name. He was keen to try anything new, and before either adopting it or abandoning it gave it an exhaustive—and to his dressers instructive—trial. Hence, amongst other reasons, the great demand for a dressership in his wards. Bryant was a bold though careful and neat operator. He used his knife without hesitancy, and anything but a clean cut was abhorrent to him. The medical operations, if I may so style them, were few in his day, but he never hesitated to act at the request of his medical colleagues, even if there were no precedent for it, if he honestly thought there was a reasonable chance of success, and he has told me that he was the first to explore a 'perityphlitic' swelling and found the 'date stone,' though he never suspected, as no one then did, any connexion with the appendix. As a colotomist he had a wide reputation, and I know, since I often assisted him in private, that many cases from abroad sought his aid. A summons once took him to Constantinople to one of these cases, an occurrence of which he was justly proud. These were, of course, the days of the lumbar operation, when if the peritoneum were by chance injured a fatal peritonitis was

THE WAR

THE CASUALTY LIST

When H.M S *Formidable* was sunk in the English Channel in the early hours of New Year's Day her three medical officers were on board, and the Admiralty assumes that they have lost their lives. Their names are Fleet Surgeon Godfrey Taylor, R N , Surgeon William Mearns, R N , and Surgeon Septimus Hibbert, R N V R

THE AMBULANCE CONSTRUCTION COMMISSION

This is the first great war in which field motor ambulances have been extensively used It was inevitable that many defects should be found in existing types, and in various quarters experts began to ask whether something could not be done to standardise the patterns and to improve the type At the instance of Mr Henry S Wellcome, founder of the Wellcome Bureau of Scientific Research, a commission has been formed, and the names of members show that the matter is regarded as of high importance by those most intimately connected with the welfare of the wounded soldier

Sir Frederick Treves will act as chairman The Admiralty is represented by the Director General of the Medical Department, R N Surgeon General Sir Arthur May, while the Quartermaster General to the Forces, Major General Sir John Cowans, and the Acting Director General, Army Medical Service, Surgeon General Sir Alfred Keogh, represent the War Office The British Red Cross Society is represented by Sir Frederick Treves, and the St John Ambulance Association by Sir Claude Macdonald and Sir John Furley The remaining members are Lord Montagu of Beaulieu, Professor W E Dalby, F R S Mr John Robertson, and Dr Andrew Balfour (honorary secretary and treasurer) This commission will act as a judging committee for the award of prizes of the value of £2000 provided by the Wellcome Bureau of Scientific Research These prizes are offered for the best designs of an ambulance body which shall fit a standard pattern motor chassis for field motor ambulances The last day for the receipt of competing designs is June 30th, 1915 It is hoped that the competition will bring in a number of ingenious designs from which the ideal field ambulance body will be evolved

The reason why the competition is restricted to designs for a body and not for the complete ambulance, including a chassis, is that a chassis takes much longer to build than a body, and that, when war breaks out, it is impossible to get at short notice anything like a sufficient number of any one type of chassis On the other hand, a standardised body to fit any chassis of approved dimensions can be constructed in numbers at comparatively short notice Moreover, a perfected body is badly wanted to ensure complete comfort for the wounded

It is hoped that the information obtained by the competition, and in other ways, will be published in some permanent form, available for future reference Probably, in addition to one design of special excellence, there will be submitted various ingenious suggestions which may be incorporated in the pattern design approved by the commission For these a portion of the prize money has been set apart The first prize is of £1000 the second of £500, and the third of £300 All details of conditions may be obtained from the secretary, the Ambulance Construction Commission, 10, Henrietta street, Cavendish square, London, W The competition is open to citizens of all nations, and designs may be submitted up to June 30th, 1915

FRENCH STATISTICS OF THE WOUNDED

The French Army Medical Service recently published figures showing the percentages of French soldiers wounded in the present war who are, or are likely to be, fit to return to active service The approximate percentages up to Dec 1st last were given as follows —

	Per cent
Wounded but now returned to the front	54 50
Wounded and on convalescent leave	24 50
Wounded and under treatment in hospital	17 40
Discharged as unfit for further service	1 46
Died from wounds	3 40

It will be noted that these add up to more than 100 A former member of the Cabinet has written to us suggesting that corresponding figures, showing the mortality from wounds and the percentages of complete and partial recoveries in the British Expeditionary Force, would be of profound interest to medical men and military students We hope the Army Medical Department may be willing to furnish such returns

THE BRITISH RED CROSS SOCIETY —In its summary of work accomplished during the week ending Jan 2nd the British Red Cross Society states that the number of auxiliary home hospitals accepted by the War Office to date was 662, containing 18,418 beds, including 1124 accepted during the past fortnight The following additional ambulance cars were despatched 8 ambulances, 1 touring car, 1 soup kitchen, and 1 motor cycle to Dunkirk , 2 ambulances and 1 touring car to Boulogne , 1 ambulance to Southampton , and 4 ambulances to Bishop s Stortford Five medical men have been engaged for service in Serbia and two for Montenegro, and are ready to leave when required During the past fortnight the Red Cross hospital at Netley has been very full, and a number of entertainments were held at Christmastide The contractors have begun work upon the "Irish Hospital " Between Dec. 29th and Jan 2nd 712 cases from the stores department were supplied to 98 hospitals—67 English hospitals and 31 foreign hospitals—and a large number of garments were received and distributed A list is received daily by the society from Boulogne containing the names of officers reported missing, and reports from brother officers or soldiers stating what they know about these When the reports are considered reliable they are forwarded to the relatives, and copies are also sent to the War Office Every wounded man journeying to England is handed a postcard on the boat, whereon he gives the name of the hospital to which he is going, and this enables his relations to find him at the earliest opportunity A great number of daily callers are received inquiring for missing officers, and every endeavour is made to trace these through the Paris or Boulogne offices Daily correspondence is maintained with Geneva, the Prisoners of War Bureau, and the Allies Relief Committee

AUSTRALIAN MEDICINE AND THE WAR —Our Melbourne correspondent writes, under date of Nov 23rd — ' The departure of the first Australian contingent was accomplished without serious accident The health of the men had been good while at the training camp In a force of about 8000 there were some 60 cases of measles, this disease being prevalent then These were treated at the Infectious Diseases Hospital, Fairfield Several deaths occurred in the Melbourne Hospital from pneumonia among soldiers transferred from the camp The Australian hospital unit is about to leave next week It will occupy a ship under Red Cross conditions for the voyage and will require no convoy A staff of 780 people will be on board which will be subsequently divided among the different hospitals to be established Particulars have already been given as to these [1] A further contingent of men is now in training the spleen in two cases, but only two, of splenic leukæmia at a time when leukæmia was rarely recognised until the spleen had become enormous, and when the supreme difficulty of checking hæmorrhage in a highly leukæmic patient had not been fully recognised The substitution of torsion for ligature of arteries was another innovation about that time, which he adopted with great ardour and employed successfully, I believe that in his later years he was regarded as being somewhat behindhand in the matter of antiseptic and aseptic surgery, but it could not have been from any disagreement with the principle of such treatment, for I well remember that he tried, enthusiastically and hopefully, Lister's treatment in its first phase—namely, the thorough dressing of wounds with carbolic oil

---

[1] THE LANCET Oct 2 th (p. 10[illegible]) and Dec 5 h (p 133[illegible]) 1914

Mr Bryant was a good colleague He took his fair share of the administrative work of the school and hospital, was punctual and exact in his attendance, and always courteous, considerate, and helpful in committee or council He wrote attractive and valuable articles in the *Guy's Hospital Reports*, and frequently contributed cases from his wards to the 'Mirror' of THE LANCET I will leave to others to appraise the merits of his book on the 'Practice of Surgery,' about which he took an immense amount of trouble and which at its first appearance was unique amongst British works in the profuseness of its illustrations, and had a pronounced success "

Sir Dyce Duckworth writes —" I was brought into close relation with Mr Bryant for some years on the General Medical Council, and I have none but kindly remembrances of him He took his duties seriously, and was always a pleasant colleague who laboured diligently in the Council, and in his study, at its committee work. We represented our respective Royal Colleges and the English Conjoint Examining Board I did not always see eye to eye with him on some matters in the Council when it became necessary to withstand opposition, but such little differences never ruffled his kindly nature or cooled our friendship for a moment I can bear no worthy testimony as to his surgical skill and teaching, but I always regarded these as expressive of the recognised soundness of the Guy's school of surgery of his day He was tenacious of all that he felt sure of, and his convictions were certainly founded on a large practical experience I am sure that he was esteemed by his colleagues, his pupils, and his patients as a tender hearted and sympathetic man, and one cannot doubt that his record as a surgeon will surely add to the reputation of his school —*Exstinctus amabitur idem* "

A CENTENARIAN —The death is announced at Newry of Miss Ellen Byrne, who is said to have been the oldest woman in Ireland, having reached the reputed age of 115 years

BRISTOL INFECTIOUS HOSPITAL —At the last meeting of the Bristol city council it was decided to increase the isolation hospital accommodation by extensions at the Novers Hill Hospital The scheme is estimated to cost about £7700, and will provide for 24 additional beds and increased accommodation for the staff

DONATIONS AND BEQUESTS —The late Mr J H Burley, of Leamington has bequeathed £5000 to the Leicester Infirmary for a " Burley Ward or for beds to be called 'Burley Beds' and £2000 each to the Leicester Institution for the Blind the Children's Hospital Leicester the Home for Incurables, Leamington, and the Cancer Hospital, Fulham.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND

DURING the week terminating on Tuesday, Jan 5th, the subscriptions announced below have come in, and the correspondence which has been received by the secretaries shows that interest in the movement is spreading The objects of the Fund which aims at alleviating the misfortunes of Belgian doctors and pharmacists, both those remaining in Belgium and those who are refugees with us, have been seen to concern closely the two professions in this country, and the response to appeals for the Fund has been considerable A number of representative men have joined the General Committee

An appeal is now being distributed by the Executive Committee of the Fund, which it is hoped will be followed by more general support

The subscriptions which have been received up to Tuesday evening last by the honorary treasurer, Dr Des Vœux, in addition to £2505 previously announced, and not including the subscriptions received in Dublin, are as follows —

	£	s	d.

The Melbourne University held a special final examination for any students who were anxious to volunteer for service and whose period of work was satisfactory No concession was made as to standard of pass work. Four candidates presented themselves and all were passed Several very well known members of the Victoria profession are included in the hospital unit about to leave They are Dr Henry Maudsley, Dr J, W Springthorpe, Dr G A. Syme, Dr T P Dunhill, and Dr J W Barrett On Nov 21st the departing Victorian medical men were entertained by the members of the Victoria Branch of the British Medical Association at a farewell dinner Complimentary speeches were made, and Dr Springthorpe stated that on the best authority he was able to say that Australia had contributed more money to the Red Cross Association in proportion to population than any other community The Australian Medical Federal Council opened a subscription list for the supply and maintenance of motor ambulance facilities for the Australian hospital unit Already over £700 has been subscribed by medical practitioners, although the fund is only a fortnight old "

Care of the Wounded in Edinburgh —Our correspondent writes "100 wounded and disabled soldiers drawn almost entirely from Scottish regiments arrived in Edinburgh from Southampton on Dec 31st The majority of them had come direct from the firing line, and many still had the mud of the trenches on their coats, kilts, and puttees They complained of the weather and of the condition of the trenches, but were enthusiastic about the way in which they were being treated as regards clothes, food, comforts, reliefs, &c Of the 100 men about half were wounded, and the remainder were suffering from frost-bite, rheumatics, or pneumonia, testifying to the rigorous conditions under which the war operations are being conducted Several members of the 8th Royal Scots (T F) were among the number The 100 men were distributed as follows Craigleith Military Hospital, 50 , Dalmeny House, 35 , and the Deaconess Hospital, 15 For the purpose of stimulating recruiting for all the battalions of the Royal Scots regiment and for enrolling the names of men eligible for a 'Bantam battalion,' for submission to the War Office after the Royal Scots regiment is up to establishment and organisation, has been formed ,with Lord Rosebery as prime mover Rest-rooms for sailors and soldiers have been opened at No 9, Croall place, Leith walk under the auspices of the Edinburgh Branch of the British Women's Temperance Association, and are provided with comfortable club rooms where leave time may be spent "

The Treatment of Cholera —Dr A G Newell, of Assam, has published[1] particulars of four cases of Asiatic cholera at Lahore treated with tincture of iodine internally Three of the cases recovered, two being natives and one a European (female), these were adults The fourth case, an infant of 18 months, died. The adult cases were severe ones, and were proved bacteriologically to be true cholera. The dose administered was one minim of tincture of iodine in water every hour or half hour until decided amelioration of the symptoms, and thereafter at longer intervals until recovery Dr Newell found that the germicidal action on cholera vibrios was distinct, even in a 1 per cent. solution of tincture of iodine, about equal to 1 in 4000 of iodine, after 24 hours, and in a 10 per cent solution after 10 minutes This shows the theoretical efficacy of iodine and that the treatment is rational Iodine tincture allays vomiting and acts as a disinfectant It is of course impossible to draw any conclusion from four cases and as the outbreak was coming to an end the type of case would naturally tend to become milder and more amenable to treatment

Vacancies for Medical Officers —We are asked by the Assistant Director of Medical Service of the 1st London Division Territorial Force to state that there are vacancies for several medical officers in the field ambulances of the 1st London Division, T F These units are now training at their war stations and the rank and file are of exceptionally good quality Officers must be duly qualified and registered medical men Applications should be made by letter or in person to Colonel J Harper A.D M S 1st London Division, T F , Headquarters, Lea Crowborough, Sussex, and will receive an immediate reply Captain C G Kay Sharp asks us to state that his unit—the Eastern Mounted Brigade Field Ambulance (Reserve) R A M C (T F), stationed at Luton, Beds —requires three medical officers to bring it up to the full war establishment Applications should be made to the officer commanding the unit, at Luton There are still a few vacancies for officers in the 2nd East Anglian Field Ambulance Reserve unit. Pay and allowances will be as in the regular Royal Army Medical Corps, and immediate application should be made to Lieutenant-Colonel Blake Masson, 148, Broadway, Peterborough.

The Union Jack Concert Party —"Will you help the Union Jack Concerts ?" is the question which Miss Helen Mott (violoncellist) and Miss Florence Castelle, writing from Dr and Mrs F W Mott's house, 25, Nottingham place London, W , put to our readers, and through them to the public, supplying excellent reasons why the answer should be in the affirmative The Union Jack Concert Party provides a weekly entertainment to wounded soldiers and sailors in military and other hospitals, and also assists at least two or three different necessitous artists at each concert, by giving them a small fee for their services Concerts have already been given at the 4th London General Base Hospital, Denmark Hill, St George's Hospital, 1st London General Base Hospital, Camberwell, St Bartholomew's Hospital, 2nd London General Base Hospital, Chelsea (Christmas Eve) , University College Hospital, and Queen Alexandra Hospital, Millbank (New Year's Day), at which the following well known artists, amongst others, very generously came and gave their services Miss Ellaline Terriss, Mr Ben Davies, Mr Lewis Sydney, Mr Nelson Jackson, Miss Ruby Helder, Mr Harold Montague, Mr Ernest Shand, Miss Cicely Courtneidge, Mr Harry Tate, Miss Wish Wynne, Mr Albert Whelan, Miss Violet Loraine, Mr Harrison Hill, Mr Jock McKay, Miss Margaret Balfour, and Mr Jack Pleasants During the next few weeks the Union Jack Concert Party will be going to the Dreadnought Hospital, Greenwich , 3rd London General Base Hospital, Wandsworth , Royal Free Hospital , Queen Alexandra Hospital , and Great Northern Hospital Anyone who could see the keen apppreciation and enjoyment of the "Tommies" during these little perfomances would we are sure, gladly support the work. All contributions will be gratefully acknowledged by Miss Helen Mott and Miss Florence Castelle (25, Nottingham place London, W) who are acting as honorary secretaries as well as giving their artistic aid

The Treatment of So-called "Frostbite"—Dr J Porter Parkinson, senior physician to the Queen's Hospital for Children and to the London Temperance Hospital, has sent us the following brief note —"During the past few weeks large numbers of soldiers have been invalided from the front suffering from a painful affection of the feet due to prolonged standing in the trenches Several of them have told me that after having been 24 or 48 hours in the fighting line they were removed to rear trenches where they took off their boots and socks and warmed their feet before a fire The feet became numbed and exceedingly painful the pain extending up the portion of the leg covered by the boot and above the ankle On admission to hospital there is little to see as a rule, the foot may appear slightly congested, with prominent subcutaneous veins But at night, when the pain is greatest, some slight swelling and blueness of the feet is visible Though feeling numb, there is no anæsthesia to touch prick, heat or cold In addition there is often a superficial gangrene of the skin at the extremity of the big toe or one of the other phalanges The condition resembles erythromelalgia, and is no doubt due to prolonged damp and cold acting on the vasomotor and sensory nerves of the feet

I would suggest that as soon as possible after the soldier is relieved from the trenches the feet be thoroughly rubbed to restore circulation and not be heated artificially before a fire , and such orders might be given by the commanding officer, who could point out the danger of omitting it As regards treatment of the cases, elevation of the feet by a pillow under the lower part of the legs is a great comfort while I have had real success from the administration of antipyrin grs x. with aspirin grs xv thrice daily The result is that the pains in the feet are usually quite gone in 48 hours ' pomp as if there was no more danger than in an ague, that is the truth, if in a *dead man there can be danger, I thinke* there is least in a dead Turk, especially a rich man then in any other, for they wash the body, though never so poor—and then with rowlers of wood squeeze out all the excrements they can, then after it is cleansed they stop all the passages with cotton. I always counted the cloaths more infectious than anything. The sick Turks this time fled into country houses and up the Bosphorous, and by their means the plague was scattered almost everywhere for 10 or 12 miles round ... We have an English apothecary here who went about dayly. At last it fell in his house and seized his wife's sister, too far for remedies to take place. She dyed, but his wife and several others escaped by your incomparable *bezoarticum animale*, whereof I have now had good tryal. There was a little boy belonged to one of my Lord's servants formerly, the father came to me for something for it, telling it had convulsion fitts. I asked him if it were not *morjack*—for so the Turks call the plague. He assured me no, no but the next morning the boy was dead. He himself soon sickened, with a dose of your *bezoarticum animale* and a saffron water which I made here he recovered, and his wife likewise. In August he was smitten again—a thing I think very rare. He sought no more to me but dyed. Feare is a horrid companion in time of pestilence, I thank God I had banished that. Your Jews all, and poor Turkes, Greeks and Armenians, live so abominably nastily and in such narrow filthy streets and so many clustered together that it is a marvel to me that the plague should ever cease untill it had swept them all away, yet it is now quite over and the streets so full of people as none seem to be wanting ... I suppose you have heard of their eating of opium. It is very true, and I assure you moreover I know one whom I have seen take the quantity of a hazel nut at a time, and he tells me he cannot live without doing it at least three or four times a day, and I have seen an Arab, that is a messenger sometimes between Aleppo and this place, take above a dram at one time by weight. It presently gives them *keif*, makes them exceeding pleasant but an houre or two after they are as dull as logs, yet I do not find in them any remarkable drowsiness at all. Many that are used to it in their *romazan*—their fast—when it is death if it be known that anyone eats the least thing imaginable from sunrise to sunset, the forbearance of this their *keif* destroys them."

---

[1] The Treatment of Cholera a Cure by A. G Newell M D Lahore: Civil and Military Press 1914 Price Rs 1.8

Abigail Harley to her Father, Sir E Harley, at Brampton—"London, June 25 1687—My aunt Bromfield has spoken to Dr Windebank concerning my mother drinking waters and his opinion is that all waters are very improper for a cancerous tumour. He says Hoxton waters would be least prejudicial, as there is nothing of alum or steel in them, but advises to meddle with none."

Edward Harley to Lady Harley—London July 7, 1688 a letter enclosing the following prescription for a water for an ulcerated cancer for his mother's use "Scrape lead very thin with a knife boyle it wel in good spring water and with it frequently wash the sore. Let it be fresh lead every time you make it the same will not serve."

Edward Harley to Sir Edward Harley—"Aug 7, 1688—Mr Fisher has told me of a spring upon Malvern Hills that had cured some years since a cancer in a lady's breast who came from London to use it. Since then it has grown famous for curing sores by bathing them there."

Sir E Harley to Robert Harley at Brampton—"1689, Aug 10—Mr Geldsthorp sends in a box camomile flower lime tree flower and black cherry water for the child, to be mixed or taken singly to remedy wind."

Robert Harley to Sir E Harley—1694 Dec 3—My wife has sent some of the Countess of Kent's powder of her own making. If it be thought fit for my brother to take he may take as much as will lie upon a sixpence at any time of the day. The ingredients are Contrayaria, Bizoar, crab's claws viper's skin jelly &c.

The Same to the Same—1694 Dec 27. My Aunt Foley sayth she experiences a chain of gold about the neck is good to keep the throat clear."

Henry Guy to Robert Harley—"1695 January—Though I have the greatest mind in the world to come to see Mr Harley—for I have had the small pox and therefore cannot fear them—yet he is not so farre advanced in his recovery as to warrant him for much talking for which cause I presume to give you the trouble of telling you the discourse which I have heard both learned and experienced persons make concerning the methods to be used at the departure of this disease. Some say that letting blood againe is good but all agree that there must bee very often purging for the infirmity which our King labours under came purely from not purging enough after it. They likewise say that after sufficient purging it is absolutely necessary when he is in the country, to go into asses milke for six weeks, or some such rule to rectify the whole figure of his blood which this distemper had corrupted."

Henry Guy to Sir E Harley—"1698, Sept 20 London—*I am infinitely concerned* at the unfortunate accident which has happened to your son, and the more because there were so many hours between his fall and the letting of blood the only remedy for such a mischance, and which must be repeated to prevent fully any future ill in the head."

The Same to the Same—"1698 Oct 4, London—Your letter gave me much ease of mind concerning your son, though I confess I do not like the bad blood appearing at the second bleeding. It plainly shows that there is bad blood to be fetched away. The head has suffered most in this accident and the physicians say that the letting blood in the foot has the best effect on the head and so likewise has cupping on the shoulders or back, but for the prevention of any future consequence nothing is so good as two issues in the shoulders just by the neck. This draws away all bad humours from the head and is a sure remedy against apoplexy, epilepsy and many of those diseases."

Robert Harley to Sir E Harley—"1700 July 25—I am extremely sorry to hear of your indisposition. I mentioned the doctor being against your bleeding, but he says you would find relief by blisters upon your arms, on the inside about the binding. I have now one on each arm from which I have found great relief."

The Same to the Same—"1700, July 27—Dr Radcliffe desires you will not do anything more to your knees and legs than keep them warm. Blisters on your arms will relieve your breast. For the cough, besides the use of such things as conserve of roses he commends the frequent use of ground ivy leaves made and drunk as tea, sweetened with sugar candy, as also the swallowing a clove of garlic often over night to preserve the stomach against goutish humours."

Dr William Stratford, of Christ Church, Oxford to Edward (afterwards Lord) Harley—"1724 Oct 14—Yesterday I had the honour to hear from my Lady Oxford, with an account of her having been confined for a week to her chamber, and that she was going to Lady Paulet. Her Ladyship mentions not to me what her illness was, but if it was the cholic I am certain there is no other safe certain remedy for it but the Bath waters. Radcliffe [Dr John] who would allow the Bath good for nothing else, owned it was a specific for the cholic."

The Same to the Same—"1725 Oct 21—I hope the little one will have no gripes that are dangerous. I would only hint that our friend Radcliffe was for giving young babes as little as possible. He frankly owned he knew not what to do with them, and was for leaving Nature, if it were possible, to do its own work."

"QUI ME ALIT ME EXSTINGUIT"

To the Editor of THE LANCET

SIR,—The war is compelling us to manufacture our own drugs for ourselves. It may perhaps teach us to rely a little more on our native abilities and output in medical science. The British student, isolated from the Austro-German schools may at last be induced in greater numbers to employ his own faculties in original research, instead of quoting foreign authorities and humbly swallowing the schematic dubieties of Frankfort and Vienna. The notion that these schools are better than our own is certainly fostered by the self satisfaction of the Germanic brain, which noises abroad its own contributions to science while ignoring or belittling those of Britain and France. Yet the young graduate will be no worse off by remaining in London or Edinburgh and learning to respect his own nation, not as such but for the sheer weight and splendour of its scientific achievements. He should then acquire self trust and the power to think and work independently. And for encouragement let him invoke such august shades as those of Newton and Faraday, of Harvey and Hunter, of Syme, Young Graves, Lister, and Darwin.

I am, Sir, yours faithfully

Liverpool

EDMUND HUGHES

THE ROYAL NAVAL DIVISION

WE have been asked by Lieutenant D Bywater R N V R Acting Adjutant of the Royal Naval Division Public School Battalion, to draw the attention of our readers to this battalion which is being raised from among public school and university men between the ages of 18 and 35 for service during the period of the war. The strength of the corps will be 1000 and it is strictly limited to men who are included in the above definition. Medical men and medical students, in view of the special need for their present and future professional services are very wisely discouraged by the military authorities from serving as combatants, but they can use their influence with others of their own class who are eligible to join such a corps *d'élite* as this Public School Battalion. Applications should be made to the Royal Naval Division, 6, 7, and 8, Old Bond street, London, W

SIDLAW SANATORIUM—Resident Medical Officer Salary £125 per annum.

WORKSOP VICTORIA HOSPITAL AND DISPENSARY—Medical Officer and House Surgeon Salary £150 per annum with rooms coal, light and attendance

THE Chief Inspector of Factories Home Office London S W gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Barnard Castle in the county of Durham.

Births, Marriages, and Deaths.

BIRTHS

BENETT—On Dec 30th 1914 at Trelaske Dallington Northampton Maude Elizabeth, the wife of Captain A M Benett, R.A.M.C of a son

COOKE—On Dec 31st 1914 at Berkshire Villa Ventnor the wife of Reginald T Cooke M R C S Eng L.R C P Lond, of a son

EMRYS-ROBERTS—On Dec 30th 1914 at Romarys Radyr Glamorgan, the wife of Professor Emrys Roberts M D of a son

GAUNTLETT—On Dec 27th 1914 at Oakhill road Putney S W the wife of Lieutenant H Leon Gauntlett, R A.M C, 6th Gloucester Regiment of a son

HOWITT—On Jan 2nd at Chesham street Belgrave-square S W the wife of A B Howitt, M D of a daughter

MANNERS RIDGE.—On Dec 24th 1914 at New River House Enfield Middlesex the wife of the late Edwyn Manners Ridge F R C S Eng, Lieut R N V R Lond., of a son

MARRIAGES

LATHBURY—BURTON—On Dec 30th 1914 very quietly at St Andrew's Eastbourne Arthur E A. Lathbury M R C S L.R C P to Lucy Burton fourth daughter of the late John Burton of Beckenham

PEDLER—RIDEAL.—On Jan 2nd. at All Saints Church Finchley road by the Rev J W Mills assistant priest George Henry Pedler of 235 Knightsbridge to Mary Alice widow of Arthur W Rideal of 54 Finchley road At home Knightsbridge Hotel Feb 2nd and 4th from 3 30 to 6 P.M

DEATHS

HEDDY—On Dec 31st 1914 at 29 Warwick road Ealing W Laura Mary the dearly loved wife of Wm Jackson Heddy M R C S Eng late of 46 Redcliffe-gardens S W

KENNEDY—On Dec 28th 1914 at Brigstock road Thornton Heath James Price Kennedy M B Ch.B

LAING—On Dec. 25th 1914 suddenly of heart failure Ernest Alexander Ronald Laing M.R C S L.R C P &c aged 42 years.

LOCKERBIE.—On Jan. 3rd at Nurse Porter's Nursing Home, Carlisle William Lockerbie M.B Ch B of Annan aged 37 years

VAWDREY—On Jan 1st. at Plymouth George Vawdrey M R.C S L R C.P aged 67 years

N.B—A fee of 5s is charged for the insertion of Notices of Births Marriages and Deaths

Notes, Short Comments, and Answers to Correspondents.

EDINBURGH UNIVERSITY AND THE WAR

A VERY interesting souvenir has been issued by the University of Edinburgh It consists of the University's "Roll of Honour," in the form of a booklet containing the names of 16 members of the University who have died "pro patria" of 14 wounded, and of 2 prisoners, together with upwards of 1600 names of teaching staff, clerical staff, technical assistants, servants, and others, graduates and alumni, and present students, now serving their country in various arms and ranks The total number on the roll at present is 1679, but the list is admittedly incomplete The medical profession is naturally well represented In the navy the University provides 85 commissioned officers of whom four have lost their lives in action, while in the army there are 517 officers, 108 serving in the ranks, and 66 auxiliaries "Our Lord Rector" (F M Lord Kitchener) forms an appropriate frontispiece

THE PROBLEM OF SERVICE

To the Editor of THE LANCET

SIR,—How can the ordinary middle aged medical practitioner be of use to his country in the present crisis? If he is willing to give up his practice, would he be acceptable for the R A M C if aged between 40 and 50, and if so, in what capacity or rank? Are commissions granted for special purposes—e g, medical officer to hospital, recruiting, &c—which do not involve leaving home?

I venture to think that some authoritative statement on the whole subject would be welcome to many of us who are anxious to offer such services as we may be capable of

I am, Sir, yours faithfully,
BARKIS

Jan 1st, 1915

*** The above is typical of a great many letters which we have received from readers during the past few months The answer must depend on individual circumstances A medical man of 40 who is strong and active and is not in regular practice might well apply for a commission in the Territorial Medical Service, in which there are still a number of vacancies for medical officers to reserve units As stated in our last issue the War Office is introducing greater flexibility into this branch of service, which should render it more attractive to medical men who wish to serve their country but are prevented from giving entirely unconditional offers of service—ED L

MEDICAL NOTES IN HISTORICAL MANUSCRIPTS

(Continued from p 56)

OUR readers were introduced last week to an interesting series of excerpts possessing a medical bearing and taken from family documents relating to the Harley family, which are now preserved at Welbeck Abbey These excerpts covered a period of some 40 years, commencing from 1633 The series is now extended for a further half century—namely, to 1725

Dr J Covell to Peter Dent—"Constantinople April 4 1684—Here hath been all this summer as hot a plague as hath happened in the memory of man About the middle of August there dyed fifteen hundred a weeke and upwards, of all sorts, Turks, Jews, and Christians I went abroad daily yet durst not venture to see any gardens either at Strombol or Scutary All our nation held very well For my own part I took nothing but a good draught of wormwood wine in the morning, and chewed zeduary as I walked abroad, and every afternoon punch—a liquor well known to sea men—was all our drink, whereof we took a good dose, and amongst other nations—whereof all had some dyed—it is certain that they that drunk hardest escaped best I was not att all afraid, yet I have been in danger a thousand times, sometimes very desperately One could not pass from our house to Galata without meeting the dead carryed out Most that died were poor people whose diet all summer is most upon cowcumbers corpooses—which are a sort of water melon gourd—and such kind of trash, and they dyed like rotten sheep, not one in ten that were smitten escapt What you commonly talk in England of the Turks not shunning the plague I will assure you is true only in the mean people which is the same among both Jews, Greeks and Armenians They value it not half so much as we do the smal pox in England, never shun one another's company only when they die very fast the corps is not accompanied with any or very few besides the priest sometimes not with him. If a great man dies there is as great a funeral

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor"

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index and Title-page to Vol. II of 1914 were given in THE LANCET of Dec 26th, 1914

VOLUMES AND CASES.

VOLUMES for the second half of the year 1914 will be ready shortly Bound in cloth, gilt lettered, price 16*s*, carriage extra.

Cases for binding the half year's numbers are now ready Cloth, gilt lettered, price 2*s*, by post 2*s* 3*d*

To be obtained on application to the Manager, accompanied by remittance

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows —

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Offices, 423, Strand London, W C

TO COLONIAL AND FOREIGN SUBSCRIBERS

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS WILLIAM WOOD AND CO, 51, Fifth Avenue, New York, U S.A.

EMERGENCY CLEANING OF INSTRUMENTS

To the Editor of THE LANCET

SIR,—Many years ago I found that the special indiarubber made for the use of typists, which I believe is a mixture of rubber and emery, was also good for cleaning rust spots off scissors, knives, and so forth, and also certain metal parts of the typewriter itself, and I have many times recommended its use, especially in emergency Now and again I see it recommended in popular journals The emery, or whatever it is, is in such a fine state of division that while it cleans well it does not scratch the instrument I had occasion once to recommend it to a surgeon who was going to perform some minor operation, and he was well pleased with it and said that it was a new notion to him

I am, Sir, yours faithfully,

London, January, 1915 TYPIST

THE BRINE BATHS OF BIARRITZ

IN addition to its climatic advantages Biarritz possesses brine springs, and there is a well appointed saline bath establishment situated about 500 yards from the seashore on the road to Bayonne, in the centre of well laid out gardens Every facility is given for treatment, which consists of baths, douches or shower baths, local applications in the form of compresses and irrigations, and massage under water The waters are very strong and contain 307 grammes of salts (chiefly sodium chloride) per litre, or about 11 times the saline strength of sea water The springs occur at Briscous, a few miles distant, whence it is conveyed to the elegant thermal establishment through pipes, the supply equalling 2000 gallons per 24 hours if required The cases which receive benefit are chiefly those in anæmia, however caused, and so forth The surroundings are attractive and the climate is described as, at the same time, bracing and sedative

THE BRITISH PHARMACOPŒIA, 1914

SOME of the wholesale drug houses have issued "Notes" on the new Pharmacopœia Messrs C J Hewlett and Son, Limited, 35 to 42, Charlotte street, London, E C, intimate that they will be glad to send a copy of their useful leaflet on this subject post free to any medical man on request It deals in a concise way with the additions, the notable omissions, and the principal alterations

◆

H R and A H—Something must be allowed for the general circumstances of the war, which, also, specially affected the publication in the direction complained of The publishers have announced their intention of returning to the previous shape The publication of an appendix would be a very expensive proceeding indeed

Miss E Piggott—We cannot trace the quotation and there is no reference to the matter in our Analytical Records

H L Morris and C H W—See page 46 of our last issue

COMMUNICATIONS not noticed in our present issue will receive attention in our next

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Remarks

ON THE

ESTIMATION OF PHYSIQUE AND STAMINA FOR SCHOOL PURPOSES[1]

By ALFRED A MUMFORD, B Sc Vict,
M D Lond,
MEDICAL OFFICER, MANCHESTER GRAMMAR SCHOOL

By "physique' we generally imply the attainment of such bodily structure and organisation as enables a person to put forth mechanical energy through the muscular system By "stamina" we generally imply the capacity for sustained vital activity, particularly when endurance has to be sustained against disintegrating influences, whether of strenuous work or of disease. The two qualities, though often closely allied, are by no means identical. Thus the medical examination needed for the study of physique of the British soldier, for candidates for cadetship in the Naval and Mercantile Marine Service, or for enrolment in the municipal Police Force is concerned primarily with the exhibition of physical energy On the other hand, medical examination in the case of candidates for participation in the benefits of a life assurance company, is concerned with stamina or stability It regards capacity for resisting the disintegrating forces of the various diseases and accidents that occur in modern social life—i e, the persistence of life rather than its power is under consideration.

The standards of physique hitherto prevalent have been largely those referring to adult life, or at least the later period of adolescence When we apply such standards to children we are faced with the fact that, even if we succeed in measuring the present powers of children, we are still a long way from being able to estimate the powers latent within, for the forces of growth of the mental and physical powers of the child are both hidden and incalculable and never stand still. This is particularly the case at the early stages of their secondary education. At first sight the problem seems insoluble, but I think further study will suggest where we may get enlightenment, though not entire solution

Standards of bodily growth as standards of physique—Pignet, a French military surgeon about 1900 made some studies of "robustness" of soldiers, and attempted to determine their physical force in terms of a formula which should express the relation between height, chest girth, and weight This formula is known as Pignet s factor, and essentially consists in saying that if from the numeral indicating the height in centimetres there are subtracted the two numerals representing chest girth in centimetres and the weight in kilogrammes, a numeral is obtained which in the absence of organic disease bears constant relation to general bodily vigour

Standards of nutrition are generally of more value for school purposes than standards of growth, at least for the early ages of life, for growth is only one of the results of nutrition Standards of nutrition are particularly necessary when considerable numbers of under nourished children exist in a group which is under review Soup kitchens for the poor preceded the establishment of popular national education in this country and abroad In France school canteens were established as early as 1867 From the time that J R Mayer proved the physiological application of the doctrine of the Conservation of Energy, and the consequent interrelation of bodily nutrition and the manifestation of power, it was inevitable that the consideration of the work expended in all the forms of activity and in growth that occur during school life should be accompanied by attempts to estimate the capacity of the child attending a public elementary school in terms of bodily nutrition, particularly under those conditions in which it was evident that adequate provision for obtaining food did not exist in the home

Standards obtained by grading according to type—A method of grading has been suggested by Mr Cecil Hawkins,[2] mathematical master of Haileybury College, which I have used extensively and find of great value in detecting departures from proper growth. Mr Hawkins has analysed some 40,000 measurements of height, weight, and chest girth of middle class boys which he had collected. He grouped them into their proper ages of 6 months interval from 10 to 18 years He has taken each group and separated it into 20 divisions, so that each division represents 5 per cent of the total measurements for that age There were therefore 5 per cent of all the boys of that age who were of that particular height, weight, and chest girth. Each of these divisions was then named as Grade 1, 2, 3, and so on to 20, so that by looking up the index book you can see whether a boy was among the biggest 5 per cent, the next tall 5 per cent, or the lowest 5 per cent We thus have the opportunity of grading any particular boy among his fellows of that particular age If he is not normal, and his weight does not correspond with his height, his grading in the three qualities will not correspond. He may be among the tall boys for height and not among the heavy boys for weight Moreover, if measurements be taken at successive periods of his life, say every 12 months, we can note whether the boy remains at one particular grade in his height, weight or chest girth, at 12, 13, 14, 15, we can also note whether his weight or his chest girth, which was at one time in proportion to his height, begins to fall off at 16 and 17 This is a common result in boys who are specialising in scholastic work. The great value of this method of individual grading comes out when we desire to estimate the stress of school life during later adolescence At 15, 16, and 17 the indoor life or the restricted food of the scholars begins to tell on bodily physique

Estimates based on medical inspection of children—The estimates or criteria suggested by the experience of medical inspection and examination of adolescent children attending school and hospital tend to separate into two groups —

1. Those which depend on the *rate and degree of bodily development* Among these by far the most important, in my opinion, is the period of eruption of the permanent teeth, particularly the canines, the bicuspids, and the second permanent molars There is considerable degree of variation in the age at which the several organs and systems of the body pass from their childhood to their adolescent stage The eruption of the teeth is the least subject to disturbance, and one may safely say that if all the bicuspids and the second permanent

1 Adapted for the exhibition of massive weight The whole physical frame here is very big The large muscles of spine, shoulder, hip and thigh, neck and upper arm are coarse fibred and well developed The movements are frequently slow, but they give one the impression of considerable power This condition may occur both among the dull and the clever boys

2. Adapted both for bodily agility and bodily strength. The bodily frame here is often less massive in build, though large and well knit The muscles of upper arm and shoulder, though not big, are still well developed and full of tone, and are fitted for rapid and effective action. The neck is long and thick and well set on the trunk and the body held very erect The chest, though not necessarily deep, has wide range of action, the difference between inspiration and expiration may be as much as 4 or 5 or more inches Such a boy is a born boxer, swimmer, runner, or athlete, and will develop in any direction he chooses to train his powers

3 The third type needs particular care and supervision during school life if he is ultimately to put forth his full innate powers The larger limb muscles and the bony framework are comparatively feebly developed. The nervous energy, though it may be very considerable in amount, is irregularly distributed, and tends to manifest itself either in some special handicraft or in some special intellectual channel, such as great language facilities, or its near ally, the mathematical faculty, or great imaginative faculties Here we need constantly to distinguish between sustained strength and short lived excitability, for, with rapid expenditure of nervous energy, rapid exhaustion is apt to set in. The sense of fatigue that should precede exhaustion and warn us of its near approach is apt to be absent Owing to the small size of the bodily muscles these children make a poor show when tested by nutritional standards or by standards of bodily physique To understand them properly we need to remember that though their intelligence or their dexterity is well in advance of their fellows, yet other parts of their physical frame are often behind. They are as childish in some directions as they are advanced in others We call them precocious children, and it is tempting to stimulate the growth of their brain instead of waiting for, what is for them even more necessary, the corresponding growth of their bodies Such children are at a further physiological disadvantage Being thin, they radiate heat very quickly, and consequently need a larger amount of food, particularly in the form of fat, than they often get This is a great difficulty among the clever poorer class children, where the higher cost of the hydrocarbons is apt to be considered in the household budget

It is in the direction of proper school treatment of such children that medical inspection of secondary schools often finds its hardest task. When tests of intelligence, of understanding, and of memory of these children are made, it is found that they range high They show keenness in school, and the form master, who only knows them during school hours, is apt to rate their powers of sustained work as high as their ready response Only the watchful parent realises how soon such powers are exhausted and what price is paid for school brightness It is necessary to direct special attention to the time such children go to bed, for their lack of stamina causes their bodily powers to resemble those of children of a younger rather than of the older age They need more sleep than their fellows of similar age Such boys also often retain the emotional qualities of childhood for a longer period than their less mentally endowed companions This matter requires particular consideration when they are to be punished. They are often unbalanced and uncontrolled, and it may be actually backward in accomplishments other than those in which they show precocity Most serious of all, such children retain the infantile susceptibility to bacterial invasions for a longer time than their more robust fellows, and at 10, 12, 13, and even 15 or 16, they are still unduly susceptible to the tonsillitis, rheumatism, sore throat, whooping cough, and other germs which their tougher comrades more readily resist Apart from their susceptibility to the tubercle bacillus, which, considering the opportunity for adequate nourishment and care that the middle class boy now possesses, is not often a very grave school danger, we need to consider their susceptibility to the micro organisms of rheumatism, with its endocarditis and chorea For this class of boy I believe that an illness, such as general rheumatism, chorea, &c, may be even more serious than an infection of tubercle

The physique of the modern secondary day school boy—It is sometimes stated that the increased urbanisation of modern life has led to a diminution in physique A complete record has been kept of physical measurements of the boys at the grammar school since 1881 All the measurements for the years 1881 to 1886 have been collected and averages taken. Similarly, the measurements from 1905 to 1910 were taken. Altogether somewhere about 7000 measurements have been utilised. Careful comparison shows that the modern boy is taller, broader chested, and heavier than the boy of a generation ago[4] He also maintains his level in athletic outdoor activities and more than maintains them in University attainments (*Vide* Physique of the Modern Boy, Manchester Statistical Society, December, 1912)

FROST-BITE

BY A. W MAYO-ROBSON, C V O, F R C S ENG, D Sc,

MAJOR, R.A.M.C (T F) THIRD LONDON GENERAL HOSPITAL.

THE advent of severe weather accompanied by frost and snow has added another terror to war in the trenches in the shape of frost bite of the feet, followed in many cases by gangrene and loss of one or more toes and occasionally by more extensive destruction of the feet Experience in this country of the class of cases under consideration has hitherto been so limited that many surgeons of large hospital experience and the greater number of nurses have up to the present never seen or treated cases of gangrene due to exposure to cold.

In ordinary frost bite the action of cold leads to death of the tissues by shutting off the arterial blood supply, but as the obstruction of the blood supply usually occurs slowly, venous stasis marks the early stages, so that the extremities—the parts usually affected—assume a slaty blue colour, become numb, and are quite cold to the touch. Not only according to the degree of cold and the length of time the damaged parts are subjected to it, but also according to the treatment adopted to restore the circulation in the early stages, will be the degree and extent of the damage to the extremities The effects of frost bite may be molars are well displayed by the age of 11½ to 12 years the child is well ahead in his physical development, and if some of them are delayed beyond 13 years of age, we should look out for signs of delayed development in other organs.

---

[4] See tables published in annual report of medical officer to the grammar school Manchester 1910

Standards of cardiac efficiency stated in terms of cardiac abnormality detected by ordinary physical examination of the chest are quite inadequate for school purposes and often misleading. The established methods of physical examination of the chest give us, it is true, certain information as to the existence of previous disabling disease. This information is, however, often misleading, and standards of cardiac efficiency based solely on it are often deceptive. This is particularly the case in auscultatory phenomena. Knowledge based on this does not sufficiently put us on our guard against the temporary cardiac and circulatory debility following acute febrile conditions such as influenza and tonsillitis. It does not tell us of damage done to the vasomotor apparatus by such diseases as diphtheria, nor does it guide us much in deciding upon the degree of efficiency of the heart muscle to withstand strenuous exertion. Dr Clement Dukes long ago (Second International Congress on School Hygiene) wrote "No physician can certify that the boy can run, although he may be able to say that he cannot."[3]

The principal school activities which call for cardiac efficiency are (1) Gymnastic exercise, including Swedish exercise, apparatus work, (2) outdoor games and sports, running, jumping, and general school games, cricket, lacrosse, football, &c., and (3) swimming.

Swedish exercises, as generally practised in schools, involve very little strain on the circulation, though they are capable of being carried to a considerable degree of severity under special conditions, but such excess is not a general rule. The exercises centre round respiratory and free limb movements. It may be said that almost any boy who is fit to attend school is also fit to attend the usual Swedish exercises, and yet medical certificates are constantly sent to school debarring boys from "all gymnastic work," which includes or is mainly composed of Swedish drill, to the great detriment of many who would be benefited by moderate exercise.

The strain that swimming exerts on the circulation is somewhat different, for there are here three facts to be considered. 1. The effort put forth by the good swimmer is much less violent and less rapidly exhausting than the effort put forth in ordinary racing and sports. This is owing to the buoyancy of the water, though in the case of a poor swimmer there is such excessive and useless expenditure of energy that the exercise may be violently acute. 2. There is a much greater demand upon heat production owing to the rapid radiation and conduction of heat from the body that occurs in the liquid as distinct from the atmospheric medium. Consequently the spare frame suffers more than the frame with better endowment of subcutaneous adipose tissue. 3. The natural reflex contraction of arteries and capillaries in response to the lowered temperature of the water causes the arterial blood pressure to rise, and in many persons causes the fingers to go white and numb. There is no real disadvantage if the immersion is only short, and if the vascular constriction gives way rapidly when vigorous bodily movement outside the water is encouraged. If it does not give way speedily, bathing should be prohibited. Under any circumstances, where it occurs the use of the cold bath should be very much restricted.

Estimation of physique and stamina by examination of the respiratory apparatus.—The changes which occur during adolescence in the respiratory apparatus are equally well marked. The chest, which was circular in infancy, becomes slightly oval in childhood. It is difficult accurately to estimate the chest girth of a child under 8 or 9 years old, unless exceptionally well developed. The narrowness of the lateral diameter of the chest causes the shoulder blades to protrude so that the chest circumference varies with the position of the arms. The chest becomes still more markedly oval during adolescence. In the case of vigorous children, the ribs are held well forward and free play is noticeable between the sternum and the costal cartilage, so that at each full inspiration the anterior part of the ribs tends actually to leave the sternum behind. As the movements take place freely and fully in all directions the bases of the thorax participate, so that on a lateral inspection of the bare chest we notice a vigorous lifting up and pushing forward of the whole sternum, instead of an antero posterior flattening of an imperfectly expanded chest, whether this is associated with defective respiratory muscular power or with lymphatic enlargements causing obstruction to the entrance of air in the upper respiratory tract. In examining the chest of the young adolescent, then, we need to note the difference between a deep and a shallow thorax, and to note the degree of bending backwards of the upper or bending forwards of the lower portion of the spine that so often accompanies the rounded shoulders of those whose respiratory range is very limited.

Estimate of physique and stamina based on the condition of the musculature of neck and spine.—In regard to scoliosis in adolescent school life the significance of the milder forms is by no means clear. Many of them are physiological and are due to unequal development of the two sides of the body. Such require general outdoor existence. A certain limited amount of spinal weakness is due to pure fatigue in children who are of defective muscular power. Its occurrence during school life is generally ascribed to bad posture during school hours. In such cases I think it is wiser to turn attention first to school curriculum even before scrutinising minutely the school furniture, and to see whether the natural body balance cannot be restored by greater attention to physical development and change of occupation and position rather than by consideration of desks, seats, &c. Still more potent as a cause of minor spinal curvature and defective neuro muscular control is the circulation of toxic products of disease, rheumatism being especially a frequent cause both of minor spinal curvature and flat foot. It is quite rare to see these cases without an antecedent history of rheumatism, chorea, or tonsillitis.

Estimates of physique and stamina based on consideration of the general muscular build.—It is essential to have clear ideas of the width of the physiological range that exists in the development of the neuro muscular system in different individuals, quite apart from the pathological results of past disease and ill health. There are practically three natural physiological types of development of the neuro-muscular system.

Routine Orders, Nov 23rd, 1914, a copy of which is appended

353 FROST BITE, PRECAUTIONS AGAINST

Cold is likely to give rise to frost-bite when the circulation of blood is interfered with or rendered feeble

The feet are likely to be frost-bitten under the following circumstances —

1. When boots and puttees are too tight
2. When the general circulation throughout the body is less active than normal
3. When the socks, boots, and puttees are wet

The best precautions are on the following lines —

1. Boots should not fit tightly, but should be at least a size too large When large boots are worn it is well to wear two pair of socks, but this is dangerous if the boots are small, as it leads to further pressure on the foot. Puttees should never be applied tightly
2. The general circulation can be kept up by keeping the body warm and dry A mackintosh sheet worn over the greatcoat is of assistance where no waterproof is available.
3. A dry pair of socks should be carried in the pockets when available.

Officers should see that dry standing is provided in the trenches whenever possible by means of drainage, raising of the foot-level by fascines of brushwood or straw with boards on top, or by the use of pumps where these are available

RESULTS OF CLINICAL INVESTIGATIONS BASED ON THE METHODS OF ABDERHALDEN

BY J O GAVRONSKY, M R C S ENG, L R C P LOND, M D,

(From the Hale Clinical Laboratory, London Hospital)

THE first edition of Abderhalden's book on defensive ferments appeared in April, 1912, while a fourth edition of the same work, very considerably enlarged, was published in April, 1914 An English translation of the third edition was also published in the early part of 1914[1] During this period the separate publications dealing with this subject have exceeded 300 in number[2] These facts indicate very clearly the great interest shown by the medical profession in the problems connected with the ingenious theory evolved by Abderhalden as to the means of defence possessed by the animal organism against the invasion of disharmonious substances Further, they show a marked appreciation of the importance of any possible application of his theoretical views to the practical side of medicine No one has realised more clearly than Abderhalden himself that, once the possibility of a *specific* test was established, it was only a matter of time and perseverance before the application of the test would be extended in all possible directions And when he considered that the methods worked out by himself and used for years in his studies on ferments generally—that is, the dialysation process and the optical method—were capable of demonstrating the existence of specific ferments in the case of pregnancy, he drew from this fact every possible conclusion as to the applicability of the test to the study of malignant tumours as well as to numerous other problems of medicine

The practical value of the test has since been experimented with all over the world, and the cardinal question is still undecided There is still, and probably will be for many years to come, a considerable divergence of opinion as to the possibility of demonstrating the presence of specific ferments in the blood serum, and of making use of such demonstration for diagnostic and other practical purposes Were this possibility once established we should attain the solution of many problems of primary and vital importance It is not, of course, a diagnosis of pregnancy in the first week that is going to bring about a serious alleviation in human suffering, moreover, gynæcologists will readily agree that it is very rarely that they are in doubt as to the differentiating between an ectopic pregnancy and a salpingitis, or between a pregnancy of the first few months and a myoma Of real importance would be the fact that one could make an early diagnosis of malignant tumours, or give a prognosis, after operation in a case of malignant disease, or differentiate between hysteria and epilepsy in doubtful cases

For more than a year I have been examining patients with a view to assuring myself of the possibility of demonstrating specific ferments in the blood serum The annexed table only shows the results of cases examined during the first six months of last year, from which time I have been able to work with an established technique and under properly favourable conditions, in a laboratory specially fitted up for the purpose and supplied with the best apparatus During the first part of the time I had to struggle with many difficulties in trying to avoid the possible errors arising out of the complicated technique

It is with great pleasure that I offer my thanks to Professor Abderhalden for the courtesy he showed me last summer on the two occasions that I visited his institute I am also much indebted to the medical officers of the London Hospital, as well as to Dr J Kennedy Will, superintendent of the Bethnal Green Asylum, for their kindness in allowing me to examine their cases Dr P N Panton, director of the Hale Clinical Laboratory, has repeatedly undertaken the bacteriological control of sterilised water, serum, dialysates, and contents of polariscope tubes, and rendered much help both by his keen interest in the subject and his friendly assistance

On the accuracy necessary in the employment of the technique no one has insisted more strongly than Abderhalden himself, and it has become customary for workers in this field to give a fairly detailed account of each stage of their procedure if they wish to avoid any suspicion of inaccuracy in method Now, in dealing with this aspect of the case it must be remembered that all methods are based on details of two kinds—namely, such as are of primary and universal importance, and such as are secondary or personal only Thus, if we are dealing with the estimation of the opsonic index, it is clear that the exactly equal amount of time given to the incubation of the actual test and of its control respectively is of primary importance, while the exact means employed in spreading the mixture of leucocytes, bacilli, and serum on the slide have only a personal interest So, too, in the Wassermann reaction the preparation and standardisation of the antigen are of the first importance, but whether one uses a capillary tube or a test tube when making a mixture of the necessary constituents will be a matter of personal preference only

In Abderhalden's methods also there are several details of secondary importance I shall not dwell on any of these secondary details, but shall only give an account of such as are obviously primary marked by mere congestion and œdema, analogous to chilblains of the feet, by more acute inflammation with blistering of the involved parts, or by gangrene more or less extensive

---

[1] Defensive Ferments of the Animal Organism (John Bale Sons and Danielsson) THE LANCET May 16th 1914 p 1399.

[2] Out of this number only 14 have appeared in the English language chiefly in the American medical journals.

The gangrene resulting from frost bite is associated with venous stasis, it therefore assumes a dark brown and later a blackish colour, which clearly defines it from the living tissues It often happens that parts apparently gangrenous may be only affected superficially, so that a toe may live and become useful an inch or more beyond the line of demarcation of the skin Dark patches on the soles and heels are usually superficial and should be left to nature until separated, when the deeper layers of the skin that remain can be covered with epithelium

In the treatment of frost bite it is of the utmost importance to save as much of the injured extremities as possible, and as it is impossible to say how much of the damaged tissues will survive, immediate or early amputation is absolutely contraindicated In some of the cases admitted to the Third London General Hospital the feet quite up to the ankle were livid in appearance, cold to the touch, and absolutely devoid of sensation three to four days after being frost bitten, yet under treatment complete recovery, or recovery with gangrene limited to only portions of the toes, resulted An important factor in producing tissue death in frost bite is the destructive changes that take place in the blood corpuscles exposed to excessive cold within the engorged veins

It is a well known fact that the frozen parts cannot be subjected to the action of heat in any form without great risk, as too rapid thawing leads to inflammatory exudation and the danger of gangrene from pressure Experience has shown that the best treatment at first is friction with snow or cold water in a cold room, the changes to a warmer atmosphere being gradually brought about Frictions with turpentine and oil or with spirit and soap liniment are useful remedies in the early stage, and after the friction the limbs should be raised on pillows and swathed in cotton wool, which can be held in position by bandages applied loosely so as to avoid any danger of constriction If blisters form, or discoloration of the toes or other parts shows that gangrene is probable, the whole foot should be sterilised by rubbing with oil of turpentine to cleanse the skin or with spirit containing 1 in 500 biniodide of mercury, after which strips of sterilised double cyanide gauze should be applied between the toes and the same gauze made to cover the whole foot, which is then enveloped in sterilised cotton wool Any blisters—which will be found to contain dark blood stained fluid—should be snipped and carefully dried and dressed with the spirit and biniodide lotion Painting the foot with tr iodine would probably be quite as effectual, as an antiseptic, as the spirit and biniodide solution

Every effort should be made to keep the parts dry and sterile, and if gangrene occurs the surgeon should on no account make too great haste to amputate, as the tissues adjoining the line of demarcation become more and more healthy and the line of granulation tissue between the dead and living tissues, if kept aseptic, gives rise to little discharge and can be kept aseptic by a daily dressing with the spirit solution Ultimately, when it is seen what flaps of skin are available, the dry, shrivelled gangrenous parts can be removed and the bones severed at such points as will allow the flaps to be conveniently applied to make a good cover to the stump Where the gangrenous process has only involved the superficial layers of the skin, the separation of the necrosed part should be left to Nature and afterwards skin grafting will be found useful If as the result of neglect or the use of wet dressings the gangrene has assumed the moist variety and the wounds are infected, the spirit dressing will still be useful, and the foot should be well dusted with equal parts of zinc oxide and boric acid, so as to make every effort to convert the moist into dry necrosis, and thus to avoid general septic complications and the danger of the gangrene spreading

In frost bite, especially of the first and second degree, great pain is often felt, but when gangrene supervenes the pain may completely subside The free use of opium or morphia proves beneficial, not only in the relief of pain and by securing sleep, but also by its effect on the circulation My colleague, Captain F H Humphris, has been treating a number of our non gangrenous cases by a daily application of static electricity, which seems to hasten convalescence by giving tone to the vessels and restoring the normal circulation in the feet

Prevention

The very fact that only a small percentage of those exposed to the same conditions of cold suffer from frost bite would seem to show that the condition may be a preventable one, and if that be the case it behoves those who are responsible for the foot and leg gear of our soldiers to give the matter their careful consideration Anything tight about the legs or feet that may impair the proper circulation of the blood—such as tight boots, which act by direct pressure, or too tightly applied puttees, which may possibly act by pressure on the veins returning the blood from the feet—must be injurious and may act as predisposing causes Inadequate covering to the feet in the shape of faulty or worn out boots or worn out or too thin stockings act as direct causes, as wet feet chill quickly If the feet get wet and the men have to stand for several hours in melting snow, which is a freezing mixture, the chances are very much in favour of them suffering from frost bite The danger might possibly be remedied by the wearing of high boots impermeable to wet by all men serving in the trenches It would be interesting to know if the soldiers of other armies wearing long boots and not wearing puttees suffer equally with our men, this could doubtless be readily ascertained and might prove useful

Finally, I would suggest that some instruction should be given to the men serving in the trenches both as to care in attending to the coverings of their feet and as to the avoidance of having anything too tight about their legs that may interfere with the circulation I think it would be also useful if they could have a little instruction in the methods to be employed as first aids in case of frost-bite, for every case might be saved if properly treated in an early stage The importance of the subject cannot be over estimated, as we have lost, and are losing, a very considerable number of our men from this cause, and the fact that a very large percentage of those sent home will be unable to return and will have to be invalided out of the army and to be pensioned for life makes the matter one of the first importance to the country

Since writing the above Sir Alfred Keogh has been so kind as to furnish me with the Army edition of Abderhalden's "Abwehrfermente" was made use of, as well as his separate articles in the periodical medical journals, chiefly the *Münchener Medizinische Wochenschrift* Thus for instance, as will be seen from the table, I began to use only 1 c.c. of serum for each test in the dialysation process as soon as I found that Abderhalden recommended this amount with the object of avoiding the appearance of a positive reaction in the dialysate of the control test. As regards details of technique recommended by other authors I found it useful to employ the process suggested by Oeller and Stephan of preparing the organs by means of the freezing method. The method of freeing the organ from blood by washing out its blood-vessels can be carried out quickly and successfully in the case of lung tissue, but is not of much help in the case of other organs, seeing that one has to spend just as much time afterwards in freeing them by the usual method.

I did not make use of a "preliminary dialysis" (the Vordialyse of Abderhalden) as it does not seem to affect the result very much, seeing that if one uses 1 c.c. of serum the dialysate of the control practically always gives a negative reaction.

In the framing of the table of results the directions given in the fourth edition have been followed. Whenever the dialysate of the control test—serum alone—gave a positive reaction the result was still marked with a –, and the results of the other tests marked accordingly—that is, e g, with a (+) instead of a + in the case where serum alone gave (+) and serum + organ gave – To indicate that the dialysate of serum alone gave a positive reaction the amount of serum used has been figured in brackets This certainly makes the reading of the results easier

Besides the control of serum only, another control was usually put up—namely serum, inactivated at 58° to 60° for half an hour, with the corresponding organ. This test does not appear in the table, as it only once happened that the corresponding dialysate showed a very slight reaction. I also tried on several occasions the use of guinea pig and rabbit serum with the view of ascertaining myself the possibility of intensifying the original reaction by these means Stephan found that the addition of guinea pig serum makes the test much more strongly positive whenever a positive reaction is expected. Occasionally I obtained a slight increase in the intensity of the reaction by adding 0 1 c.c. of rabbit or guinea pig serum to the test, but the difference is not sufficiently marked to attach great importance to this modification Moreover, as I have used the optical method in conjunction with the dialysation process, it has seemed to me advisable to indicate the results obtained by each of these methods on one line, so as to permit of easy comparison.

The different peptones are indicated by letters B = placenta peptone obtained from Höchst A, A_1, A_2 = different placenta peptones prepared by myself C = a peptone prepared from 7 cases of scirrhus of the breast L = lung peptone prepared from normal lung tissue. Li = liver peptone from normal liver tissue S = a sarcoma peptone, from a case of mediastinal sarcoma. W = Witte peptone Si = silk peptone

The table clearly shows that the results of this investigation do not confirm the possibility of demonstrating specific ferments when Abderhalden s directions are followed. The only conclusions we are justified in drawing are as follows 1. The serum of pregnant patients contains proteo and peptolytic ferments which are able to decompose any kind of coagulated albumin or peptone prepared therefrom 2 Whenever proteolytic ferments are found in the serum of patients with malignant tumours or other diseases, they have the property of acting in the same non specific manner 3 The serum of perfectly normal individuals does not contain these ferments, at least in the great majority of cases A negative result when we attempt to demonstrate proteolytic ferments in suspected cases of pregnancy or carcinoma speaks strongly against the existence of these states, and therefore may be of value in practice

After having prepared more than 60 different substrates, and having observed constantly the results of numerous tests, I am strongly of opinion that the varying degrees of intensity in the resulting reactions depend mainly on the physical form in which the substrate is presented to the ferments The more spongy the tissue, as in the case of placenta—that is to say, the more of its surface that can be exposed simultaneously to the action of the ferments—the deeper and the more decisive will be the intensity of the reaction. When, on the other hand, the prepared organ, as in the case of brain tissue, gives us pieces which are neither spongy nor dendritic in appearance, then the reaction is always less intense and more difficult to estimate, particularly so when the pieces are not sufficiently small.

And so it happens that a beginner, who has learned to prepare properly a placenta albumin, will obtain apparently specific reactions by examining only cases of pregnancy, he will get a positive reaction with placenta albumin, a negative one with other substrates—for instance, with carcinoma and with kidney albumins But let him look at the appearance of his substrates and compare them. Only by repeated preparation does one learn to prepare the substrates according to Abderhalden s directions Yet it is impossible, and everyone who has had personal experience in preparing substrates will agree to this, to make the carcinoma albumin appear in the same finely divided state that placenta albumin exhibits to the naked eye Paradoxical as it may sound, the more one follows Abderhalden's directions in the preparation of the substrates the less one is likely to meet with specific reactions A perfect placenta will give a positive reaction not only with a serum rich in ferments, as in the case of general paralysis in the last stages, or of old epileptic insanity with fits following on the top of one another, but also in a case of pulmonary tuberculosis that may fail to react with placenta prepared in a less elaborate way

Besides the placenta peptone put on the market by Höchst, which, as can be seen from the table, has proved to be a far from infallible reagent for testing pregnancy, there are other preparations brought on the market by some people who are apparently in a great hurry to make the best out of Abderhalden's promising scientific work without even taking the trouble of giving to the ' carcinoma extracts,' &c., the proper external appearance that a reagent should have when prepared according to Abderhalden's instructions Abderhalden himself is of opinion that it is premature, while the whole question is in the experimental stage, to put on the market any 'diagnostica ' I think that they can do even more harm to the field of research in question than those profound articles in which authors report on so many cases of pregnancy or tuberculosis examined without taking the trouble to examine even one normal case, or articles where every result of an occasional test is followed by learned deliberations about the rules for diagnosis, prognosis, and treatment of disease to be drawn from it

The future will show how far the investigation of the serum for the presence of proteo and peptolytic ferments will be made use of for the routine work of clinical examination There is no doubt about the great service rendered by Abderhalden to the science of physiology and to medicine by introducing and

Obtaining the serum —The blood has always (unless otherwise stated) been taken from the patient about one hour before the midday meal, and therefore on an empty stomach It was drawn off from the cubital vein by means of a dry needle, to which was attached a short length of rubber tubing, and passed into wide sterile centrifuge tubes fitted with a metal cap and having a capacity of 25 c c After standing for 1½ to 2 hours it was centrifuged for half an hour in a good electric centrifuge, starting at a slow speed and gradually increasing to the desired rate The serum was then poured off and again centrifuged for ten minutes It was then carefully pipetted off, the small disc of red corpuscles at the bottom of the tube being left, still covered with at least 0 5 c c of the serum so as to avoid all risk of drawing up any of the corpuscles The serum so obtained was practically always found, on microscopic and spectroscopic examination, to be quite free from formed elements or from any traces of hæmoglobin, and where such traces were found to occur the fact is noted under the experiment in question When the investigation was first undertaken tubes were used of a capacity of only 10 c.c In these cases it was found that the clot often adhered to the sides of the tube and did not come down to the bottom when centrifuged. Mechanical separation by means of a glass rod had to be resorted to, and hæmolysis sometimes resulted. This is avoided by using wider tubes of 25 c c capacity, and a relatively greater amount of serum can be obtained

Dialysing tubes —The tubes, No 579A, of Schleicher and Schüll, of Düren, were used They were always carefully tested for impermeability to albumin and for even permeability to peptones, and were never used more than three or four times without being re tested Occasionally the tested tubes of Schöps, of Halle, were used, but these were tested again before use Impermeability to albumin was tested by means of the biuret reaction, and later the sulphosalicylic acid test was used as a control to the biuret reaction In the case of the biuret reaction all danger of making a false personal estimate of the colour value was eliminated in the following manner A friend, who knew nothing of the experiment otherwise, was given the numbered test tubes one by one, and his estimate of the colour noted down The tubes were again given to him at random, and the values of his first, second, and even third estimates were compared for each tube When these agreed between themselves one could have no doubt as to the accuracy of his estimate, and if the slightest suspicion of doubt arose the tube in question was rejected

As concerns equal permeability to peptones they were not entirely satisfactory If we take a 0 5 solution of silk-peptone and use 5 c c of this we get a strong reaction of the dialysate with 0 2 c c of ninhydrin, but it must be noted that in this case it is not possible to observe slight differences in the intensity of the colour reaction But by using 2 5 c c of a 0 1 solution of peptone these differences become readily observable, and when this method was employed it was found that the tubes were not equally permeable to the peptone The differences observed were very slight, yet even the same series of tubes on being retested would show a slight difference again as compared with the first testing Thus they could be used only on the condition that no attention were paid to very slight differences of colour, marked differences alone being of any value

Preparation of the organs —Placenta was obtained immediately or shortly after delivery Tumours were obtained from the operating theatre, and only exceptionally from the post mortem room, in which case only fresh portions, showing no débris, were chosen. In all those cases where organs were obtained from the post-mortem room, only those were chosen in which the organs were normal (preferably cases of accident) and in which the post-mortem examination was held within 24 hours of death

When obtained, fibrous tissue, blood vessels, and nerves were cut away, and the remaining portion cut into small pieces or passed through a mincing machine This was then washed under a stream of water on a sieve, while, by continuous squeezing with the fingers and with pestle and mortar, the blood was washed out, at the same time that the small bits of fibrous tissue and blood vessels were carefully extracted Then the tissue was suspended in water and again carefully searched for fibrous tissue and vessels In the case of the placenta this operation was completed within 4 to 5 hours, on a few occasions only was it necessary to leave the organ overnight in water, as it could not be entirely freed from blood by the end of the working day Microscopic examination of the placenta, just before boiling out the dialysable substances, shows that it now consists chiefly of decidual cells, with, of course, a variable amount of fibrous tissue but no corpuscles or leucocytes Suspended in water the pieces appear snow white and spread on wet filter paper compare closely with this in colour—that is to say, they have a slightly greyish tinge A true snow white colour of the boiled organ was only obtainable by the use of the freezing method, the sections being cut to a thickness of 20 to 40 microns

The organ was then boiled out six times, 3 to 5 drops of glacial acetic being added, on first boiling, for each litre of distilled water After each boiling the tissue was squeezed out thoroughly The organs were stored in distilled water with chloroform and toluol and the bottles put away in an ice chest

When these organs were tested by boiling them out with five times the amount of distilled water they were found to be quite free from dialysable substances in nearly every instance, very occasionally they had to be boiled out again. They were also found to be quite satisfactory when examined by the other tests described in the third edition of "Die Abwehrfermente" Somewhat more stringent tests are suggested in the fourth edition, the organs, when taken at random and subjected to these, still showed themselves to be completely free from dialysable substances These latter tests may be illustrated by the following example 3 grm. of the organ are taken with five times the quantity of distilled water and incubated for 24 hours The water is then filtered off, the organ is then boiled for five minutes with the same amount of fresh distilled water, and this is then filtered through the same filter into the first filtrate The combined filtrates are evaporated down to 1 c c, 1 c c of 1 per cent ninhydrin is added and the whole is boiled for one minute No reaction, indicating the presence of dialysable substances, was ever obtained

In the actual experiments the amount of organ used was always the same for each dialysing tube used in the experiment—namely, 0 1 or 0 2 grms

Preparation of peptones —In the preparation of peptones it was found that, after evaporating the neutralised fluid to a thin syrup, and adding methyl alcohol to this and heating it, some of it dissolves and precipitates subsequently with ethyl alcohol, but that a part is not dissolved and remains on the filter paper In his fourth edition of "Die Abwehrfermente" Abderhalden points out that this may be used as well as the part that filters through It dissolves readily in water, and is sometimes greater in bulk than the filtered portion. This part, however was not made use of in this investigation The peptones contained in it are obviously of slightly different constitution to those that pass through the filter, and it seemed desirable to use peptones of as equal constitution as possible Otherwise it would certainly be advantageous not to reject them, since it is difficult to obtain much peptone from an organ Thus in the case of squamous-cell carcinoma 7 patients were required to obtain 50 grms of material, from which barely 3½ grms of peptone could be extracted

The precipitate obtained with ethyl alcohol was dried either over sulphuric acid or over phosphorus pentachloride In the first case the resulting powder was yellowish, in the second it was white In either case a 5 per cent solution of the powder was made up in physiological salt solution, and this agreed with Abderhalden's requirements in giving a rotation of −0 75° on the average, varying from about −0·90 to −0 60

The three field polariscope of Schmidt and Hänsch was employed, with a heating apparatus attached The heating apparatus was not standardised at first, it was subsequently found that there was a difference of 2° C between the reading of the thermometer and the actual temperature round the slots on which the tubes rest during examination This difference however, has been of no importance seeing that the tubes were always removed from the heating chamber immediately after examination, and replaced in the incubator

Some further remarks concerning the technique have still to be made As a guide to this part of the work the third

continuously working at the improvement of his new methods of research

At present, according to our experience, the less control one uses in examining cases the better results one is likely to get If anyone were to examine 100 cases of pregnancy and as many cases of robust healthy adults with placenta albumin only, the probability is that by proper working he would get an expected result in nearly every case examined and declare that Abderhalden's test is a specific test for pregnancy Let him now use other well prepared substrates say a carcinoma albumin, he will come to the conclusion that the Abderhalden test is not a specific one, but that the serum of a pregnant patient occasionally gives a positive reaction with carcinoma albumin If he will use besides a few other substrates—e g human and sheep's testicles and human muscle—he will find himself still more dubious as to the specificity of the proteolytic ferments in blood serum He will lose all faith in it as things stand now if instead of taking healthy people as controls, he examines patients' serum collected at random in medical and surgical wards

If someone will compare the conclusions that I have come to at the end of a year's experience with Abderhalden's methods of investigation, with my article on the subject in the *London Hospital Gazette*,[2] independently of my own experimental work, he may be surprised at the optimistic tone of the latter But there is nothing surprising in it There is a distinct difference between theory and practice Ehrlich's chain theory preceded the complement deviation test And I am still, as ever, full of admiration for Abderhalden's theoretical views on the action of ferments in the animal organism, and firmly believe that in time one will be able to demonstrate specific ferments in the blood serum[4]

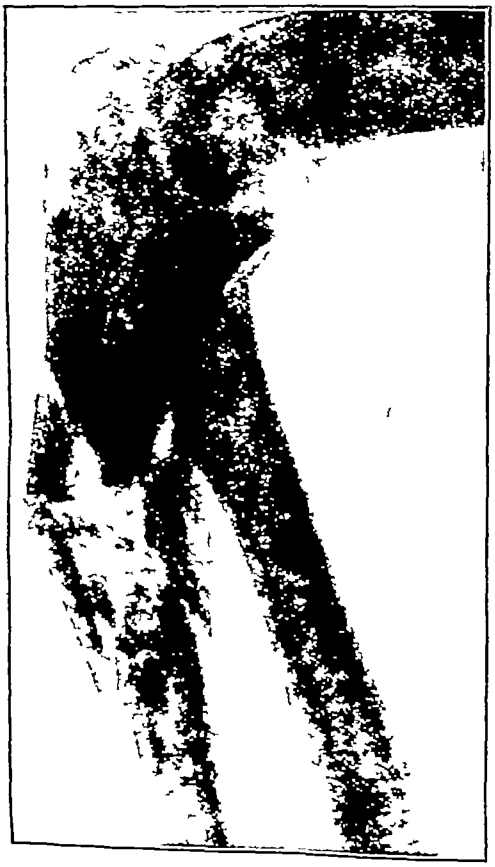
* *Primary carcinoma stomach.*

outwards from the path of the bullet The wounds both of entry and of exit were small and had healed when the patient was received at Hampstead from the Royal Herbert Hospital, Woolwich The patient had absolute ulnar paralysis below the level of the injury

In the course of five weeks the fracture became solidly united, and I then operated on the ulnar nerve, three quarters of an inch of which had been destroyed by the bullet The shortening of the nerve made it necessary to displace its upper part to the front of the internal condyle before the freshened ends could be comfortably brought together and stitched with catgut Sensation began to return a fortnight later

Fig 1.



A typical rifle-bullet fracture of the shaft of the ulna.

Case 2. *Fracture of the ulna with comminution both of the bone and of the bullet* —In this case there was only one external wound, and it was healed when the patient came into hospital The missile was probably a leaden shrapnel bullet, which is broken into fragments, as shown in Fig 2 Union was slow, but with the aid of regular massage mobility and crepitus, both pronounced at first, gradually diminished, and when the patient was discharged to convalesce the continuity of the bone was all but restored

Case 3 *Fracture of the shaft of the humerus by a shrapnel bullet* —The patient a dragoon, was wounded in the retreat from Mons, and remained in the saddle for some hours after being struck The wound where the bullet entered over the outer and lower part of the deltoid had healed when the patient came into hospital a fortnight after it was received The radiogram showed some traces of metal separated from the bullet in its passage through the bone Union was complete in five weeks and then I operated to remove the bullet which gave the patient some inconvenience It lay in the substance of the serratus and on examination proved to be a leaden sphere about half an inch in diameter Under massage and exercises the range of movement was restored to the normal and the muscular power improved

Case 4 *Fracture of the shaft of the femur by rifle bullet, which could be felt under the skin on the outer aspect of the limb as is shown in the radiogram* (Fig 3) —The wound of entry had healed when the patient, a Belgian, came into the hospital The position of the fragments was even worse than appears in the radiogram, and after four weeks there was no sign of uniting The patient is a somewhat delicate man, and like many others of the wounded or sick soldiers suffered from pyorrhœa. The latter having been energetically treated for a week previously, I dealt with the fracture by open operation The bullet lay in a cavity only slightly larger than itself and lined by granulations blackened by the stain of the metal, the nickel coat of the bullet being intact The fractured surfaces of bone were freely exposed through an antero external incision The fragments were separated by a portion of the crureus muscle, they were freshened, and a little callus was removed

The patient s condition made any long operation unwise, so an encircling loop of stout silver wire was used to hold the fragments together, the loop being itself kept from slipping by a short screw inserted into one fragment The limb was put up on a long splint and a 12 lb extension applied The position was good, there being about half an inch of shortening In this case, owing to the fragments being separated by muscle, there was no chance of union apart from open operation but it was with reluctance that I had resort to operation, because I had previous experience of

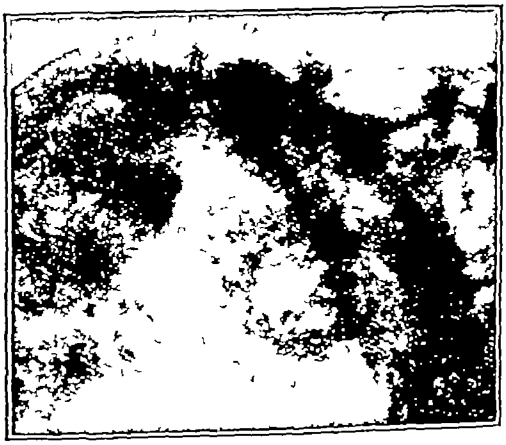
A shrapnel-bullet fracture of the shaft of the ulna.

A CASE OF X RAY DIAGNOSIS OF A CHRONIC CEREBRAL ABSCESS

SECONDARY TO FRONTAL SINUS SUPPURATION

BY WILFRID GLEGG, M D , C M EDIN ,
M R C P EDIN ,
SURGEON TO THE EAR AND THROAT HOSPITAL, BIRMINGHAM
AND
HAROLD BLACK, M B , B CH BELF , M R C P LOND ,
RADIOGRAPHER TO THE QUEEN'S HOSPITAL, BIRMINGHAM

THE patient, a private on the Reserve list of the 2nd Battalion Royal Warwickshire Regiment, was sent to the Ear and Throat Hospital by Mr Beatson Hird on acount of the persistence of discharge from a fistulous opening in the right frontal region, in the lower part of a depressed scar above the inner end of the right eyebrow The history was as follows In April, 1913, the patient attended the eye department at the General Hospital with symptoms of acute inflammation in the right frontal sinus He complained of pain, and in the upper part of the right orbit there was an inflammatory swelling, which was incised by Mr Hird Carious bone was detected in the orbital roof, and through a necrotic area a probe could be passed into the right frontal sinus The patient was sent to the surgical side, where a radical operation was performed on the right frontal sinus, the particulars of which have been supplied by Mr H. H. Sampson, resident surgical officer The right frontal sinus was a shallow one Its entire anterior wall was removed, and also the mucous lining of the sinus, in a state of polypoid degeneration, showing that the cavity had been the seat of chronic disease with a recent acute exacerbation There was no sign of caries on the posterior wall An opening was found through the median partition into the left frontal sinus Drainage into the nose was attempted on the right side, and the edges of the wound were kept apart, but in spite of this the discharge continued externally from the lower part of the wound



Reproduction of skiagram showing site of abscess injected with bismuth paste

At a subsequent operation an area of carious and necrotic bone was found in the centre of the posterior wall of the sinus, and by its removal the dura was exposed Purulent discharge still continued from the wound

In September, 1914, the patient was admitted to the Ear and Throat Hospital for further treatment No evidence of disease was observed within the nasal cavities After determining the upward and inward direction of the fistula it was decided to make use of Beck's bismuth paste to demonstrate, if possible, the source of the discharge For this purpose a small amount of it was injected in a warm fluid state through the fistula and was retained for the most part Radiograms then were made on two occasions in postero anterior and lateral directions, and with some surprise it was seen that the bismuth had collected in the right frontal lobe of the cerebrum (See illustration.) Under an anæsthetic a flap was raised along the lines of the former incision to expose the right frontal bone, where an opening was found about the size of a shilling exposing the dura. The bone edges were smooth and the surrounding bone was healthy in appearance The fistulous track from the lower part of the skin incision led to an opening in the dura surrounded by granulations at the upper edge of the hiatus in the bone, and sinus forceps inserted through it allowed about a drachm of pus to escape Resistance to the passage of the forceps was felt at a distance of 2 inches from the surface After removing bone around the fistula a strip of gauze was inserted into the abscess cavity Through an opening in the median partition between the frontal sinuses several small polypi were removed from the left sinus, and the passage into the nose made wider on that side The right infundibulum had become obliterated The external wound was left open and the discharge of pus continued for four weeks, but ceased when the gauze drain finally was removed and after an application of silver nitrate had been made to the granulations around the opening in the dura. The wound now is closed, and the patient remains in good health

It is interesting to note that the patient's general state gave no indication of the presence of a cerebral abscess, owing, no doubt, to the absence of pressure from retention of the contents The fistula allowed discharge to overflow, but the drainage had been insufficient to permit closure of the abscess cavity until the operation remedied the condition The case illustrates the use of bismuth combined with an X ray examination in localising the site of the abscess before operation, and its value as an aid to diagnosis of an otherwise obscure source of a purulent discharge

Birmingham

A NOTE ON SOME CASES OF GUNSHOT FRACTURE

BY J JACKSON CLARKE, M B LOND , F R C S ENG
SENIOR SURGEON TO THE HAMPSTEAD AND NORTH WEST LONDON HOSPITAL SURGEON TO THE ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.

SINCE shortly after the beginning of the present war beds both at the Hampstead and the Orthopædic Hospitals have been occupied by wounded soldiers Among the many cases of wounds of various kinds a considerable number have involved fracture of one or more bones In studying the fractures we have had valuable help from the radiographers, Dr Stanley Melville at the Orthopædic Hospital and Mr Cyril Thatcher at Hampstead. It seems worth while to put on record a few of the more typical cases

CASE 1 *Fracture of the ulna by rifle bullet* (Fig 1).—As shown in the radiogram the fracture is typical of the damage done to a bone when it is struck vertically by a modern conical bullet travelling at a high velocity, there is a central space, and around it many fragments displaced

PELLAGRA IN ANTIGUA.

BY W M McDONALD, M R C S ENG , L R C P LOND ,
MEDICAL SUPERINTENDENT THE HOSPITAL, ANTIGUA
WEST INDIES

THIRTY TWO cases of pellagra have come under my notice here during 1913, 14 at the lunatic asylum and 18 at the hospital Five of these in the lunatic asylum came from Dominica, 5 from St Kitts, 1 from the Virgin Islands, and the remainder of the cases, 21 in number, have all originated in Antigua There have been 10 deaths from pellagra in the lunatic asylum during the year and 1 death in the hospital Pellagra was first reported in Antigua in 1909, and since then an increased number of cases have been recorded every year It is impossible to say how long the disease may have existed here, as it is a disease that has only of recent years attracted universal attention, and was not therefore looked for or diagnosed here A disease known locally as "rum burn" has long been prevalent here, these cases were most probably cases of pellagra in alcoholic subjects

Pellagra, however, is undoubtedly endemic in Antigua This fact is of vital importance to students of the disease in its bearing on (1) the opinion of the Italian medical schools and other investigators, that pellagra is a food disease caused by the ingestion of bad maize, and (2) the opinion of Sambon and certain American investigators that pellagra is an insect borne disease The bearing of this fact on the study of the disease can best be seen by comparing the theories advanced by the exponents of the two great rival theories We can then see to what extent local conditions conform to either of these theories For this purpose I submit the tables of comparison herewith attached

TABLE I —*Theories of the exponents of the parasitic theory as opposed to the maize theory*

A Sambon s reasons (1910) for believing that it is carried by an insect, most probably by the simulium fly

1 The topographical distribution of pellagra does not coincide with that of maize consumption

2 The disease occurs frequently in persons who have seldom or never partaken of maize as an article of food

3 Preventive measures based on the maize theory have failed

4 There is no foundation for the belief that pellagra broke out in Europe soon after the introduction of maize from America

5 It is not directly contagious

6 It presents a seasonal incidence—viz , spring and autumn

7 Simulium in its imago stage appears to affect the same seasonal incidence

8 Simulium so far as is known, affects the same topographical conditions as pellagra.

9 It is practically restricted to only one class of people—viz the agricultural labourer—owing to greater exposure to infection

10 Simulium has a wide geographical distribution which appears to correspond with that of pellagra

11 Pellagra stations are closely associated with streams of running water

12. That this theory of its being conveyed by simulium explains most admirably the limitation of the disease to agricultural labourers *a limitation which nothing else can explain in a satisfactory manner*

B Thompson McFadden Pellagra Commission, 1913

1 The supposition that the ingestion of good or spoiled maize is the essential cause of pellagra is not supported by our study

2 No specific cause of pellagra has been recognised

3 We are inclined to regard intimate association in the household and the contamination of food with the secretions of pellagrins as possible modes of distribution of the disease

4 We have discovered no evidence incriminating flies of the genus simulium *except their universal distribution throughout the area studied* If it is distributed by a blood sucking insect stomoxys calcitrans would appear to be the most probable carrier

5 Pellagra is in all probability a specific infectious disease communicable from person to person by means at present unknown

TABLE II —*Theories of the exponents of the maize and bad food theories*

A. Italian theories as summarised by Lavinder 1909

1 Pellagra is found as an epidemic disease only in those countries where maize is extensively used as an article of food by the *poorer classes*, although there are vast tracts where maize has been grown and used as a food for many years and yet no pellagra has appeared

2 Countries in which maize is not grown or used for food, even though contiguous to pellagrous sections, are free of pellagra (see Lombroso, Procopin, Babes, Sion and others)

3 A change of food among individuals or groups of *individuals* brings constantly a diminution or disappearance of pellagra

4 History and observation show clearly that the first appearance of pellagra in Europe followed more or less closely the introduction of maize into Europe

B Dudgeon on pellagra in Egypt 1910

1 Pellagra is undoubtedly confined to people whose staple diet is maize It is very uncommon among the rich agricultural class, though it does occur

TABLE III —*Facts from a report on 1420 cases of pellagra in Kentucky, Georgia and South Carolina 1913 by Robert Grimm, Surgeon in the United States Public Service*

1 Percentage of cases among whites, 85 7, among the coloured population, 14 3

2 Of 323 of these cases personally seen and investigated each one gave a history of more or less regular use of corn as a diet

3 Most cases had been subsisting almost entirely on food bought at the stores—viz , canned, salted, preserved foods

4 Most cases were found among renters and croppers who live under conditions of poverty and bad hygiene

5 Six cases of the 323 personally seen occurred in persons in comfortable circumstances

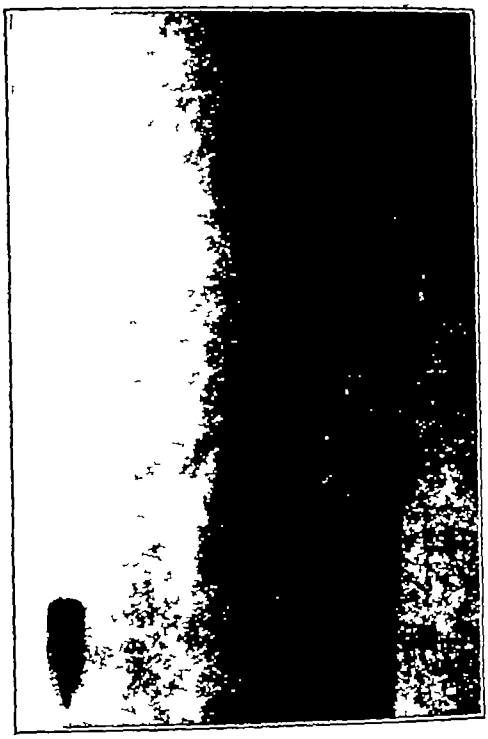
The facts of the existence of pellagra here which have special bearing on these theories are 1 Antigua was visited in 1913 by Dr Sambon, of London and by Mr Jennings, of the American Bureau of Entomology, in the course of their investigations of pellagra Neither of them was able to find any simulium in Antigua 2 There is very little running water to be found in Antigua, and none of the cases reported have any connexion whatever with running water 3 No cases have been reported among the white population, all the cases occurred among the blacks, who generally live in conditions of poverty and bad hygiene 4 All the cases have occurred among the class whose principal diet is cornmeal and salt fish. 5 Cornmeal is also largely partaken of by the white population, among whom no cases of pellagra have occurred, but in their case the cornmeal is taken in conjunction with an otherwise generous and varied diet

The first and second of these facts have a distinctly adverse bearing on the simulium hypothesis (Compare Table I A, 7, 8, 10, 11) The third of these facts may be considered first, as bearing on the stomoxys calcitrans theory (Table I B, 4) This insect is found here, and is most frequently discovered in the neighbourhood of out buildings and failure of union of fractures in subjects of pyorrhœa after open operation and in spite of aseptic healing of the operated parts Five weeks after operation there was an abundant callus, and the limb was put up in plaster of-Paris bandages to enable the patient to get about on crutches

CASE 5 *Fracture by rifle bullet of the right radius* (Figs 4 and 5) —The wound of entry was on the outer aspect of the forearm , that of exit on the front , the latter was as large as a five shilling piece, and from both free suppuration was taking place

I explored the parts and found that the loose fragments shown in the radiogram were imbedded in the wall of a cavity of the size of a pigeon's egg beneath the flexor muscles Having removed these fragments and provided for free drainage, I dealt with the broken bone in a way that in spite of theoretical objections has proved successful in my hands The fragments were drilled and a wire passed through the holes and brought out at the wound and there twisted Figs 4 and 5 show the improved position thus obtained When union has taken place the wire is removed in septic cases, whilst in aseptic conditions, the wire being firmly incorporated in the bone, the ends of the wire are merely cut off flush with the bone Used in this way the wire secures a good position of the fragments, lessens pain, and acts as a drain More elaborate modes of fixation are to be avoided in such cases Five weeks after the operation, all suppuration having ceased and union of the fragments being firm, the wire was removed, and the patient will be little, if any, the worse for his wound

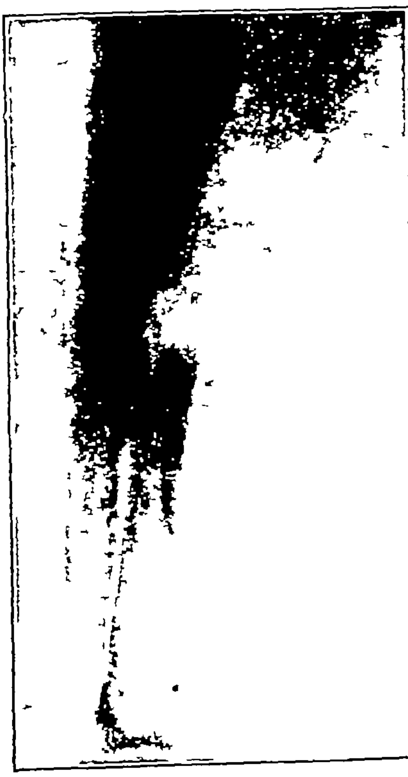
FIG 3



A rifle-bullet fracture of the shaft of the femur the bullet is seen lying close to the surface of the limb

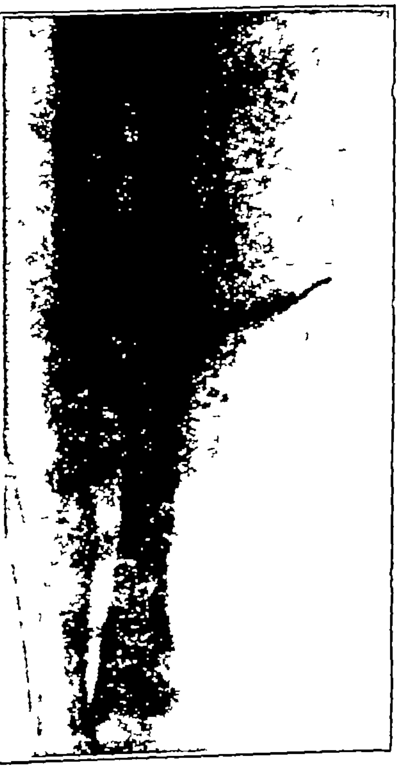
CASE 6 *Transverse fracture through the left humerus just above the epicondyles* —The patient, a sturdy infantryman, was admitted with a stiff elbow, painful and almost of double its normal width Both wounds were healed. There was partial ulnar paralysis 'A radiogram showed several fragments below the line of passage of the bullet, and some of them had been displaced laterally I opened the joint through an incision curved upwards, and this having been reflected to expose the olecranon, the latter was cut through at its base, revealing six separate fragments These I removed, then, having shaped the lower surface of the upper fragment and re attached the olecranon by a wire, the wound was closed and the limb put up on an angular splint The patient has now a useful elbow with about 90 degrees of movement. The ulnar paresis has disappeared

FIG 4



A rifle-bullet fracture of the radius

FIG 5



The same as Fig 4 after temporary wiring the author s method of treating compound fractures of long bones

CASE 7 *Fracture of the upper end of the tibia into the knee-joint* —The patient had been struck on the front of the knee by the brass cap of a shell There was no external wound The joint was distended with fluid and there was deformity of the limb, which was in the state of genu valgum

The joint was opened by a transverse cut, the knee-cap being divided across A teacupful of clot and serum having been removed, it was seen that the inner tuberosity was broken off and the fragment displaced downwards , the posterior crucial ligament was torn through at its femoral attachment. The fragment of bone was forced into place without much difficulty and the patella having been drilled and wired in two places and the synovial membrane and capsule stitched the wound was closed Three weeks later passive lateral movements of the patella were smooth and the patient will probably have a useful and movable knee-joint

In conclusion I should like to acknowledge the great assistance I have received in the above and many kindred cases from Dr G A. H. Barton, anæsthetist, and from Mr J B Truter, house surgeon at Hampstead, and Mr Renfrew White, house surgeon at the Orthopædic Hospital.

Portland place W

necessary supply of complement would be always present We already know that many of the metallic salts act in exactly this manner, and a series of experiments were performed to determine whether the same fact held true for calcium chloride

Experiment—A series of tubes was put up containing in each case 0 5 c.c. of a 1/20 suspension of washed sheep corpuscles in normal saline 0 5 c c of a 1/10 dilution of fresh guinea pig serum, and 0 5 c c. of a dilution of an inactivated hæmolytic serum (rabbit r sheep) containing 4 minimal hæmolytic doses To each tube was added a varying amount of a 10 per cent solution of pure calcium chloride, and finally the contents of each tube were made up to the same total volume by the addition of the requisite amount of normal saline solution The whole series was then incubated at 37° C for one hour At the end of this time the tubes were inspected and those which showed no obvious hæmolysis were centrifugalised and again examined

The results were as follows —

Amount of 10 / calcium chloride added.		Hæmolysis	Amount of 10 / calcium chloride added.		Hæmolysis
0·1 c c	..	Faint trace	0·04 c.c	..	Almost complete
0·09 c c	..	Trace.	0·03 c.c.	.. ..	Complete
0·08 c.c.	...	Very marked	0·02 c.c.	.. ..	"
0·07 c c	....		0·01 c.c		
0·06 c.c	...	"	0·00 c.c	.. ..	
0·05 c.c	..	Almost complete			

The supernatant fluid was then pipetted off from the two tubes showing only a faint tinge of hæmolysis To the deposited red cells were added in one case 1 c c of saline and 0 5 c c of the diluted guinea pig serum, to the other 1 5 c c of saline The tubes were well shaken and again incubated for 1 hour at 37° C At the end of this time the tube to which complement had been added showed complete hæmolysis, the tube which had received only saline showed none This experiment was repeated with varying dilutions of calcium chloride, always with the same result

These results show that calcium chloride falls into line with other metallic salts, in so far as it has no action on either the red cells or the hæmolytic antibody, nor does it prevent the combination of these two elements in the concentrations here employed For the reasons mentioned above, therefore, we should expect that its antihæmolytic action would be less in evidence *in vivo* than *in vitro*

We next proceeded to put the question to experimental proof, employing in all cases rabbits as the subjects of experiment and a hæmolytic serum which was obtained by the repeated intraperitoneal injection of washed rabbit corpuscles into guinea pigs The serum was inactivated by heating for 30 minutes at 55° C, and then stored on ice until used

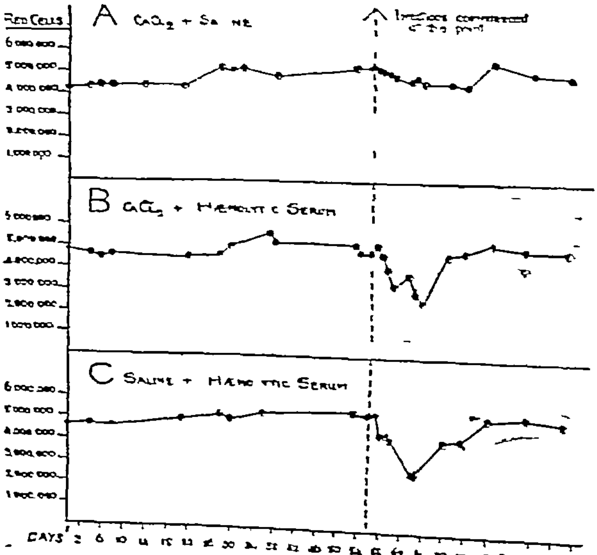
We would point out here that the experience obtained by a large number of consecutive red cell counts, carried out on individual rabbits, has convinced us that the variations in the results obtained from day to day are much more considerable than in the case of a similar series of counts carried out in the human subject The method employed was to take up 5 c mm of blood in a graduated pipette and transfer it to 995 c mm of normal saline containing 1 per cent of sodium citrate and a trace of formalin The count was made in an ordinary Thoma Zeiss counting chamber The blood was obtained by puncturing one of the smaller ear veins and in each case two exactly similar dilutions were prepared and counts made from each the results being averaged Even when these precautions were taken considerable differences between daily counts were observed, and for this reason every animal employed was kept for some weeks under constant conditions, and then several successive counts were made, so that a reliable standard could be obtained for observing subsequent variations The injections were, in almost all cases, given into the marginal vein of the same ear which had been punctured in making the previous counts The other ear was employed in the subsequent observations Blood was collected for counting from each rabbit immediately before making the inoculation.

Experiment—Three rabbits, "A," "B" and "C," were taken. To "A" was administered a series of intravenous injections of a 10 per cent solution of calcium chloride, followed after an interval of ten minutes by the intravenous injection of a certain amount of normal saline "B" was treated in the same way, except that the normal saline was replaced by an equal quantity of the hæmolytic serum. In the case of "C," saline was substituted for the calcium chloride solution, the hæmolytic serum being injected as in the case of "B." The actual injections were carried out as follows —

Day of experiment	"A"		"B"		C	
	10 / calcium chloride	Normal saline	10 / calcium chloride	Hæmolytic serum	Normal saline	Hæmolytic serum
1st ..	1 c.c	0 2 c.c.	1 c c.	0·2 c.c	1 c.c.	0·2 c.c
2nd ..		0 5 c.c		0·5 c c.		0·5 c.c
3rd		"		"	"	"
4th	"		"	"	"	"
5th				"		"
6th ..			"			"
8th		"				"

The results are clearly shown in Chart I

CHART I



From this experiment we see that a relatively large dose of calcium chloride administered intravenously does not serve to inhibit the action of a hæmolytic serum injected by the same route ten minutes later Evidence confirmatory of these results was obtained in two further series of experiments In the first series a preliminary *in vitro* experiment was made and the exact quantity of calcium chloride necessary completely to inhibit hæmolysis by 0 1 c c. of the immune guinea pig serum in the presence of a relatively large excess of complement (fresh rabbit serum) was determined stables which are the places frequented by the blacks and not frequented by the whites (Compare also Table I A, 9, 12) This fact is also of very great importance, in view of the fact that Grimm, in investigating 1426 cases of pellagra among whites and blacks both living under bad economic conditions, found that 85 7 per cent of the cases occurred among whites, and this in a community in which he states the negroes equal or probably outnumber the whites He further states that in several districts he was told by physicians that they had met with several cases of pellagra among whites, but had never seen a case among the blacks His facts justify him therefore in drawing the conclusion that among blacks and whites living under the same conditions whites are more susceptible to the disease

In the light of this fact it is all the more remarkable that all the cases in Antigua occur among the blacks and none among the whites This might be accounted for by the fact that blacks are more exposed to being bitten by the stomoxys, or equally by the fact that the whites live under far better economic conditions than the blacks This fact is also of importance as bearing on the food theory, and in this connexion it must be considered in conjunction with facts 4 and 5 Fact 4 taken by itself would appear to bear out the maize theory, and is in accord with Lavinder's statement (Table II A, 1) and with Dudgeon's experience in Egypt (Table II B, 1) Taken in conjunction, however, with fact 5, its importance as a factor in favour of the maize theory is greatly minimised, and when we consider that pellagra is found among the blacks who live on cornmeal + a generally inadequate and improper diet, and pellagra is not found among the whites in Antigua who are really more susceptible to it, and eat cornmeal + an adequate and varied diet, it will be seen that the facts of its occurrence here, while not incompatible with the theory that it is conveyed by the stomoxys calcitrans, are most in accord with the theory that the causative agent in pellagra is not so much the ingestion of spoiled maize as the deficiency of some essential item of diet, in a word, that it is caused not by bad food but by deficient food This theory is in accord with many of the arguments stated in all three tables—Tables I A, 1, 2, 3, 4, 5, 9, 12, B, 7, Table II A, 1, 3, B, 1, Table III, 2, 3, 4 With regard to the infective nature of pellagra, I have not been able to trace any connexion between any of the cases which have come under my observation

Antigua

LIVINGSTONE COLLEGE —"Livingstone College Year Book," which usually makes its appearance in the summer, has this year been published in the present month, and contains a report of the work of the session 1913–14 This is the last report of the work of the College under the principalship of Dr C F Harford, who has now given place to Dr Loftus E Wigram, and the extracts received from old students of the College afford testimony of the need for such an institution and of the affection in which the late Principal and his wife are held by those who have passed through the College these numbering 548 in 21 years, the period of the existence of the College The teaching is intended to help missionaries to take care of their own health and to give them sufficient medical knowledge to deal with simple cases when qualified medical aid is not at hand The "Livingstone College Year Book, 1915" has a very good reproduction of a photograph of Dr Harford as a frontispiece, and can be obtained from the College, Leyton, E, price 6d

THE EFFECT OF CALCIUM CHLORIDE ON HÆMOLYSIS OCCURRING "IN VIVO"

BY W W C TOPLEY, M B, B C CANTAB,
M R.C P LOND,
BACTERIOLOGIST TO CHARING CROSS HOSPITAL,
AND
S G PLATTS, M B, B C CANTAB,
DEMONSTRATOR OF BACTERIOLOGY CHARING CROSS HOSPITAL MEDICAL SCHOOL.

(*From the Bacteriological Department of Charing Cross Hospital*)

IT has long been known that certain metallic salts, and especially the salts of the metals of the alkaline earth series, exert *in vitro* an inhibitory action on the lysis of red blood corpuscles by normal and immune hæmolytic sera This phenomenon was first demonstrated by Nolf,[1] and the subsequent observations of Markl,[2] Ehrlich and Sachs,[3] Vincent and Dopter,[4] Sutherland and McKay,[5] and others have all tended to confirm his results The inquiry was taken a step further by Markl,[2] who showed that in the case of the acid phosphate of sodium and certain other salts the absence of hæmolysis resulted from the failure of the complement to combine with the red cell antibody complex These results were confirmed by Ehrlich and Sachs,[3] though these authors do not accept the whole of Markl's explanation

As a result of the antihæmolytic action which they display in test tube experiments, the salts of calcium have been put forward as valuable therapeutic agents in cases in which hæmolysis is an important factor, notably in blackwater fever The treatment of this condition by calcium chloride has been urged especially by Vincent[6] and by Sutherland and McKay[5] The former asserts that, in addition to its inhibitory action against various hæmolytic sera, this salt is also antihæmolytic in the presence of the salts of quinine, to which has been ascribed by some a leading *rôle in* the production of hæmoglobinuric fever in malarial patients MacGilchrist,[7] however, has been unable to confirm these results

Since the assumption of the therapeutic value of the salts of calcium in conditions which involve hæmolysis is based almost entirely on test tube experiments, and since we have plentiful examples of the difficulties which arise in applying *in vitro* findings to the solution of problems which involve similar processes occurring in the living subject, it would seem to be of interest to determine whether the antihæmolytic action of calcium chloride is as potent in the animal body as it is in the test tube. An opinion on this point possessing a considerable degree of probability may be formed from a consideration of the way in which this salt acts If the result of its presence in a hæmolytic mixture is merely to prevent the fixation of complement by the *red cell antibody complex*, or to inhibit the action of the former without permanently affecting either the red cells or the hæmolytic antibody, then it would seem highly improbable that any useful therapeutic result could be obtained For unless the concentration of the salt could be maintained at a sufficiently high level at the site of the hæmolytic process, and as long as the hæmolytic agent was in operation, the onset of hæmolysis would be only slightly delayed, since neither the animal's red cells nor the hæmolytic antibody would be in any way modified, and the calcium chloride on red cells, which were subjected in the animal body to the action of a specific hæmolysin Indeed, any differences in the parallel experiments were in the nature of excessive lysis in the cases of those animals which were treated with this salt

It may be argued that the administration of the salt was too infrequent to admit of the steady maintenance of a sufficient concentration in the tissues and blood stream This objection will not hold if we remember the relatively enormous doses of the drug employed, corresponding to about 16 grm given intravenously to the human subject, a dose, moreover, which approached closely the lethal limit, as is shown by the death of a control animal immediately following the second injection in the last experiment, and by the fact that rabbit "B" in this series became greatly distressed after each injection of the salt We know also from the work of Mendel and Benedict,[9] Boggs,[10] and others, that the excretion of calcium is comparatively slow, and we may hence be certain that in the last experiment the concentration of the salt in the tissues was maintained at a level beyond that which could be obtained in the therapeutic administration of the drug to man

Conclusions—The experiments here described afford no evidence of any protective influence being exerted by calcium chloride on the red cells of animals subjected to the action of a specific hæmolytic serum, though this salt serves to inhibit the lysis of the same cells by the same serum in test tube experiments Conclusions as to the therapeutic value of this and similar salts based on *in vitro* experiments must therefore be held to be invalid

ROYAL SOCIETY OF MEDICINE

SECTION OF OBSTETRICS AND GYNÆCOLOGY

Exhibition of Cases and Specimens —Sarcoma of Cervix and of Broad Ligament —Cancer of Cervix —Hysterectomy for Ante partum Hæmorrhage

A MEETING of this section was held on Dec 3rd 1914, Dr W S A GRIFFITH the President, being in the chair

Mr CLIFFORD WHITE showed (1) an Ovarian Tumour which had been infected with tubercle, and (2) a case of Interstitial Tuberculous Salpingitis in which tubercle bacilli were found in a small intra mural abscess

Dr H MACNAUGHTON-JONES demonstrated a Myomatous Uterus containing large numbers of intra mural and submucous growths The tumour was removed from a patient aged 47 and it weighed 1 lb 1 oz The nuclei varied in size from that of a small egg to a pea There were three larger intra uterine growths two in the fundal cavity and a cervical polypus Altogether in this comparatively small sized tumour there were from 30 to 40 growths subserous, in the cavity and in the wall The uterine surface was studded over with them and its wall was a mass of nuclei. It was noteworthy that the patient sought advice rather for other symptoms than pelvic ones Only for the past year had she suffered from menorrhagia

Dr TREVOR B DAVIES recorded two cases—(1) Sarcoma of the Cervix Uteri and (2) Sarcoma of the Broad Ligament The first patient, a single woman aged 29, was under the care of Mr T G Stevens There had been vaginal bleeding for three weeks The menstrual periods were quite regular every 28 days, lasting from four to seven days Examination per vaginam revealed a soft, smooth, rounded, bleeding tumour growing from the anterior lip of the cervix and filling the upper part of the vagina The uterine body was normal in size and position A hysterectomy was performed, the vagina being divided well below the growth The pathological report stated that the tumour was roughly spherical and covered by a smooth necrotic surface, and in the recent state it measured 2 inches in diameter Microscopically the appearances were those of a spindle celled sarcoma The stroma was scanty and the blood vessels had very thin walls The second patient was aged 51, married, and had had two children, menopause 1¼ years ago Complaint Pain in the right side of the lower abdomen running through to the back In March 1910, Mr D Drew removed an inflamed appendix. Examination showed the appendix scar to be tender and the right kidney freely mobile Per vaginam To the right of the cervix lay a hard fixed mass the size of a large walnut, which bulged down into the vaginal roof The uterus was normal in size and position and quite separate from the mass At operation a hard swelling was found between the layers of the right broad ligament It was shelled out and the broad ligament closed In less than three weeks another fixed mass was felt in the same position The tumour was about the size of a Tangerine orange, with a small mass the size of a large cherry projecting from its upper part The tumour was pale and fairly firm, its surface somewhat nodular In section the surface was pale, there were no hæmorrhages and no vessels were seen Microscopically, the growth was a typical spindle celled sarcoma composed of large spindle cells arranged in bundles without any fibrous stroma, but with numerous thin-walled blood vessels

Dr C HUBERT ROBERTS showed a specimen of Pyometra and Cancer of the Cervix removed from a patient, aged 62, who had had seven children and two abortions, menopause 17 years ago History of severe hæmorrhage three months before admission, and gushes of putrid fluid accompanied by severe colicky pains The cervix revealed no ulceration nor new growth, uterine body enlarged, soft and mobile During the hysterectomy the vagina ruptured and foul material escaped into the pelvis The lower part of the abdominal wound became infected, but the patient subsequently did well The specimen showed a tubular solid growth of the whole of the cervix, which extended from the portio vaginalis to the os internum, and was densely hard The cavity of the uterus was distended with purulent debris The growth was a squamous celled epithelioma

Dr CUTHBERT LOCKYER showed a case of Double Ureter which simulated a parovarian cyst of the right broad ligament The specimen was obtained from a patient aged 63, in whom Dr Amand Routh had noticed an enlarged and tender right kidney for two years previously Pyonephrosis had been suspected There was coli bacilluria, for which many injections of autogenous vaccine had been given without improvement A hard, tender solid lump was to be felt in the left posterior quadrant of the pelvis In March, 1914, the patient began to lose blood from the uterus As the menopause occurred 20 years previously, this latter symptom raised the question of malignancy starting in the body of the uterus At the operation the hard body to the left of the uterus proved to be an *isolated* calcareous myoma adherent to the rectum and to the back of the left broad ligament, its shape suggested that it originally had a pedunculated attachment to the uterus Above this independent growth but quite separate and distinct, lay a solid tumour of the ovary, which proved to be malignant. The uterus and tumours were removed The right broad ligament contained a cystic swelling of the size of an orange, which proved to be a dilated ureter twisted upon itself This hydro-ureter was removed, the corresponding kidney was left *in situ* The contents of the ureter were found after operation to be two calculi (blocking the lower twisted portion) and foul stagnant urine Six weeks later a perinephric abscess was opened, since when the kidney had given no trouble The cause of the uterine hæmorrhage was two myomatous polypi and endometrial hyperplasia The uterus was not malignant

Experiment —Each tube contained 0 5 c c of a 5 per cent suspension of washed rabbit corpuscles in normal saline, and 0 1 c c of the inactivated hæmolytic serum (guinea pig v rabbit) A 10 per cent solution of calcium chloride in distilled water was then added in the amount indicated in the table, and sufficient saline was added to equalise the total volume in each tube Finally, 0 5 c.c of fresh undiluted rabbit serum was added to each tube to serve as complement Incubation was carried out for one hour at 37° C with the following results —

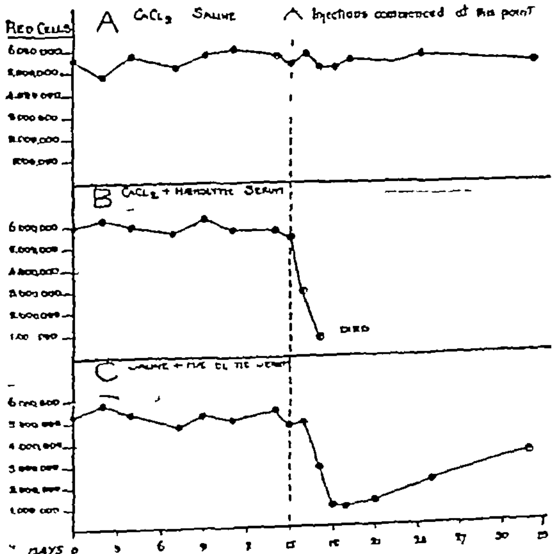
Amount of 10% calcium chloride added	Hæmolysis in 1 hour at 37° C
0 c c	Complete
0·025 ,	,,
0 05 ,,	,,
0·075 ,,	,
0 1 ,,	Almost complete
0 15 c c	Slight.
0 2 ,,	None
0 25 ,	,,
0 5 ,	,,
0·75 ,	,,
1 ,	,

Thus, 0 02 grm of calcium chloride served completely to inhibit the hæmolysis caused by 0 1 c c of this immune serum acting on rabbits' red cells in the presence of a relative excess of rabbits' complement

Now it is clear that the ratio between the amount of the calcium chloride and the amount of hæmolytic serum is the only one which we can keep constant in passing from *in vitro* to *in vivo* conditions, since the total bulk of red cells in the animal's body and the total available complement at any given time are beyond our control We know indeed from the study of Muir and McNee[8] that a serum hæmolytic for rabbits' red cells produces, when injected into this animal, a degree of blood destruction incomparably greater than one would be led to expect from a measurement of its activity in the test tube A mixture was prepared containing hæmolytic serum and calcium chloride in such proportions that no hæmolysis would occur *in vitro, and this mixture* was administered intravenously

Experiment —Three rabbits, "A," "B," and "C," were taken "A" received 2 c c of normal saline and 1 c c of a 40 per cent solution of calcium chloride "B" received 2 c c of hæmolytic serum and 1 c c of 40 per cent calcium chloride solution "C" received 2 c c of the same serum and 1 c c of normal saline All injections were given intravenously, and the two constituents were mixed in the syringe immediately before inoculation in each case Chart II shows clearly the course of events As before counts taken before as well as after the inoculations are included, and the vertical line shows the point at which these were given

CHART II

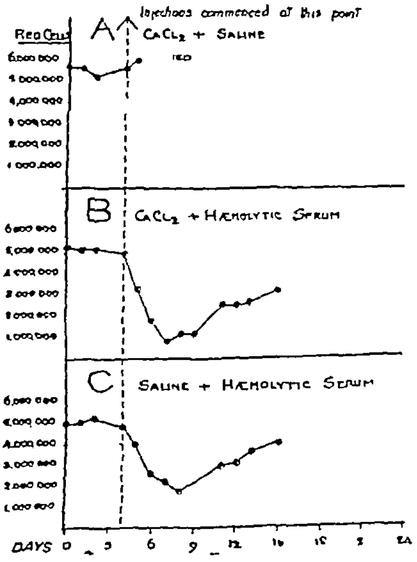


This experiment demonstrates conclusively that a mixture of hæmolytic serum and calcium chloride which produces no lysis in the test tube is actively lytic when introduced into the general circulation Indeed, any difference which is present between the two animals which *received the serum is in favour* of that one which did not receive the calcium salt *Too much stress should not be laid on the death of* rabbit "B" in this experiment, since rabbit "C" also became acutely ill and at one time appeared moribund The control animal showed some *symptoms of distress immediately after receiving* the calcium chloride injection, but quickly *recovered and remained in apparently normal* health

A final series of experiments was made in which the initial steps were identical with the above, but *the animal which received serum and calcium* chloride and that which received saline and *calcium chloride* were each *given further daily* injections of the same amount of calcium chloride *solution,* while the rabbit which was originally *given serum and saline received further daily injections of the same amount of saline solution.*

Experiment —Three rabbits, "A," "B," and "C," were taken "A" received a mixture of 2 c c saline and 1 c.c 40 per cent calcium chloride solution, and thereafter a daily injection of 1 c c 40 per cent calcium chloride until death "B" received a mixture of 2 c c of hæmolytic serum and 1 c c of 40 per cent calcium chloride solution, and thereafter *a daily injection of 1 c c 40 per cent calcium chloride* solution until the termination of experiment, except on the sixth day after the first injection, when no calcium chloride was given "C" received a mixture of 2 c c of the same hæmolytic serum and 1 c c of normal saline solution, and thereafter 1 c c of normal saline until the termination of the experiment, except on the *sixth day after the first* injection

CHART III



As before all injections were given intravenously, except that the sixth and subsequent inoculations of calcium chloride solutions into rabbit "B" were given intramuscularly on account of the fact that a large œdematous swelling had formed in the neighbourhood of the marginal ear vein used for the previous intravenous injections A similar change in the site of injection was at the same time made in the case of rabbit "C" in order to keep the results comparable The results are charted in the same way as for the preceding experiments (See Chart III)

The results obtained throughout were thus entirely *concordant* No evidence whatever was obtained of any protective action exerted by operation had been done 21 times, with three deaths. In those who survived there had been a very marked improvement.—Mr. HENRY STOKES discussed the question of sacrificing or saving the great omentum. He thought Mr. Blayney was to be complimented on the low mortality rate in these cases.—Dr. E. M. MAXWELL said she thought that the subject would become more important as time went on and methods became more exact. She suggested that the primary focus of many things would be discovered, such as inflammations of the eye. She referred to one of the cases mentioned in the paper. A patient aged 38 met with an accident to his eye; the day following she extracted a piece of iron and he underwent a normal convalescence, but at the end of a year he returned with acute iritis of the right eye. The patient informed her that during that year he was receiving treatment for constipation and dyspepsia, and about this time Mr. Blayney resected a portion of the colon, and within five days the visual power was recovered and within two months of the operation vision was as good as it had been before.—Dr. CROFTON said the operation was a very severe one and obviously, even in the most skilled hands, was attended by a very high mortality. The cases that had recovered were undoubtedly much improved and taught important lessons. Lane had shown the importance of the intestine, especially the large one, as a source of infection, but if it were possible to get the gastro-intestinal tract working without these operations it would be desirable to do so.—Sir JOHN LENTAIGNE said if the value of this procedure was to be understood and the best means planned for treating these cases the causation of the trouble ought to be known. The ideas generally held about it were very vague. He thought a perfect elucidation had been given by Professor Combe, of Lausanne, who had written two books on the subject laying down in the plainest possible way, from his point of view, the pathology and treatment of these conditions. According to Combe the essence of the trouble in all these cases was the absorption of poisons from the large intestine produced by the decomposition of nitrogenous portions of food. This bacterial decomposition of food occurred in every one, but in the normal individual there were safeguards by which it was checked, and it was only when these barriers broke down that ill health ensued. There were many other conditions which were produced by absorption of these poisons, and all of them at some time or other were amenable to medical treatment. Great improvement could be brought about by diet, but nevertheless many cases came to the surgeon, sometimes owing to an acute attack and sometimes because they objected to restriction in diet or were too poor to be able to get suitable dieting or to face the long and tedious, and more or less uncertain, medical treatment, and therefore had to be treated by a surgeon quickly. It was therefore necessary that the best treatment should be ascertained. What the surgeon saw when he opened the abdomen was probably the result of a very slow process which had gone on for years. As to the operation, Sir John Lentaigne considered that the best plan where the surgeon must interfere was to get a free emptying of the bowel and so relieve the stasis. He was entirely in agreement with Lane as to complete removal of the colon, but it was a very dangerous operation, and unless the technique was perfect the patient was very subject to sepsis. Mr. Blayney's operation, although it removed the worst part of the sink in which the putrefaction was going on, left sufficient of the large intestine to cause further trouble. He looked upon Mr. Blayney's patients as likely to be improved but not cured.—Mr. BLAYNEY in reply largely agreed with the remarks of Sir John Lentaigne as to the cause of the condition. The operation suggested by him was intended only for cases that could not be treated medicinally, and its object was to restore as far as possible the normal condition.

ULSTER MEDICAL SOCIETY.—At a meeting of this society held on Jan. 7th in the Medical Institute, Belfast (Dr. J. S. Morrow, the President, in the chair), Dr. [illegible] read a paper on Diagnosis in Phthisis. Dr. [illegible] read Notes of a Case of Acute Intestinal Obstruction Caused by a Dermoid Cyst of the Ovary, and Dr. [illegible] Robb opened a discussion on the Present Outbreak of Scarlet Fever in Belfast.—In opening the discussion [illegible]

Reviews and Notices of Books.

On Pharmacotherapy and Preventive Inoculation applied to Pneumonia in the African Native, with a Discourse on the Logical Methods which ought to be Employed in the Evaluation of Therapeutic Agents.
By Sir ALMROTH E. WRIGHT, M.D. Dub., F.R.S. London: Constable and Co. 1914. Pp. 124. Price 4s. 6d. net.

THE lengthy title of this little book somewhat recalls the titles of the pamphlets which were at one time so much favoured by learned men, and the contents of its first part correspond to some extent with such a comparison, being largely logical and polemical in character. The main thesis of this first part is the question of the value of æthylhydrocuprein hydrochlorate in the treatment of pneumonia, and certain experiments are set forth which were directed towards ascertaining the action of this substance on pneumococci in the presence of serum. Unfortunately, the results obtained in human patients are disappointing, and the drug has some tendency to affect the optic nerve and cause blindness, it is in Wright's phraseology "optico neurotropic." The rest of the first part of the book is devoted to a discussion of the methods by which we arrive at truth in scientific medical investigation, and these are, according to the author, two—viz., the experiental and the statistical. The latter is praised and practised by Professor Karl Pearson, who has thereby arrived at conclusions unfavourable to the value of the method of estimating the opsonic index of the serum devised by Wright. This may perhaps explain to some extent the latter's apparent preference for the so-called experiental method, which is a process of induction by the individual observer based on his own experience, the value of the conclusions reached depending on the character of the observer and on his carrying out proper methods of research with due control experiments. This is a little reminiscent of Aristotle's method of defining the virtues, each of which occupies a middle point between two vices, and this middle point is fixed "by reason and by the judgment of the practical man." It would seem that the practical man of one country—say, Germany—may differ from that of another—for instance, one of our own countrymen—as to the exact point where vice ends and virtue begins, and however immaterial this may be in the moral field it is inconvenient in science. "Authority" will always have weight, but decision by authority hardly constitutes a valid scientific method. At all events, the seeker for knowledge will be faced by the difficulty of determining who are the competent, and therefore authoritative, persons whose conclusions he can accept.

The second part of the book is devoted to the question of the use of vaccines in the prophylaxis and treatment of pneumonia, the subjects of observation being the native labourers in a South African mine. It seems that such natives are more susceptible to pneumococcal infection than are Europeans; that a considerable dose of vaccine—1000 millions or so—may have some prophylactic efficacy, but only for a brief period of time, and that while the administration of a vaccine during the incubative period of pneumonia may abort the attack, the use of this method in cases of the developed disease is of uncertain value. Many other interesting points are incidentally recorded, Dr **HERBERT SPENCER** described a case of Extensive Cancer of the Cervix with Pyosalpinx, well seven years after Wertheim's hysterectomy The patient was aged 28 She had been examined by an obstetric physician, who advised her to go into a cancer ward as no operation could be done The cervix was occupied by a large ulcerated growth as big as a small apple, which distended the vagina The uterus was fixed by thickening in the left broad ligament and the left sacro uterine ligament, the thickening was not nodular Operation was performed at University College Hospital on Feb 16th, 1907 The cervical growth was first curetted and cauterised, and several protruding masses were cut off with scissors A solution of formalin (10 per cent) was then applied The operation was rendered difficult owing to the presence of bilateral pus tubes, which were adherent to the pelvis and rectum The separation of the left ureter was also difficult No glands were removed A small abdominal drain was used Urine escaped by the abdominal drainage tube for a few days and afterwards by the vagina The patient recovered and left for Canada, where a vesical fistula was found and closed by Dr Marlow, of Toronto Dr Spencer examined the patient every year for four years after operation and found no recurrence In a letter dated March 24th, 1914, the patient reported herself as in the best of health Dr Spencer did not think Wertheim's operation was as good as vaginal hysterectomy with the cautery for early cases of squamous carcinoma of the portio , but for extensive growths and for adeno carcinoma it was much better

Mr **T G STEVENS** described two cases of Hysterectomy for Ante partum Hæmorrhage The first was one of central placenta prævia in a patient, aged 37 28 weeks advanced in her twelfth pregnancy She was admitted to Queen Charlotte s Hospital at 1 A M , having had a severe blood loss the evening before The os uteri admitted two fingers and the whole lower uterine segment was covered by placenta as far as the finger could reach A de Ribes' bag was introduced above the placenta, considerable hæmorrhage occurring during the procedure Subcutaneous saline and morphia ¼ gr were given owing to signs of collapse. Seven hours later the bag was expelled, the uterus was in a state of tonic contraction, and the cervix had closed up after allowing the bag to pass No further hæmorrhage occurred At this point Mr Stevens saw the patient and after debating the question as to the best method of delivering her, so as to avoid further blood loss, came to the conclusion that hysterectomy without opening the uterus offered the best solution As the child was already dead, this operation was performed under morphia atropine open ether anæsthesia, with infiltration of the abdominal wall by urea quinine hydrochloride Four pints of saline were infused subcutaneously The operation proved to be a very easy one, and was practically shockless The patient made an uninterrupted recovery The second case was one of external and concealed accidental hæmorrhage in a patient aged 33, about 30 weeks advanced in her ninth pregnancy She was admitted to Queen Charlotte's Hospital at 4 A M with the history of a big hæmorrhage at 10 P M the previous night. There was no hæmorrhage on admission, the pulse was 112–120, the patient looked very anæmic, and no placenta could be felt in the lower uterine segment The patient was kept quiet in bed, and 12 hours after admission bleeding recommenced An attempt to introduce a de Ribes bag failed owing to the rigidly closed internal os Pituitary extract, ½ c c , and a little later morphia, ¼ gr , and 4 pints of saline were given subcutaneously, after which the external bleeding ceased. The patient however, had a pulse of 150, and an examination of the uterus resulted in a provisional diagnosis of concealed hæmorrhage Seeing that the child was dead, the internal os closed, and the patient in a very serious condition Mr Stevens decided that hysterectomy without opening the uterus offered the best chance of saving the patient s life This was done under morphia atropine open ether anæsthesia with novocaine infiltration of the abdominal wall. Again the operation was very easy, and proved to be shockless the pulse falling from 150 to 134 at the end of the operation The patient made a good recovery The reason for the choice of hysterectomy rather than Cæsarean section in these two desperate cases was the impossibility of any guarantee that the latter operation could be done without further considerable blood loss Both patients had lost so much that a further loss of a pint would almost certainly have proved fatal Further, at the time that Mr Stevens saw the patients there was no possibility of delivery *per vias naturales* without a considerable loss The actual amount of blood lost during the operation in each case did not amount to three ounces, and under the method of anæsthesia chosen the operation was shockless

ROYAL ACADEMY OF MEDICINE IN IRELAND

SECTION OF SURGERY

Exhibition of Specimens —Intestinal Stasis

A MEETING of this section was held on Dec 11th, 1914, Sir JOHN LENTAIGNE being in the chair

Mr **D KENNEDY** exhibited a portion of Resected Intestine showing Congenital Absence of Cæcum and Appendix, with Atrophied Ascending Colon removed from a girl aged 20 Four years ago she had a subcostal abscess on the right side, which seemed to be shut off from the abdominal cavity The opinion formed was that it was a localised tuberculous abscess, and on opening it she made a good recovery Two years afterwards she developed a fæcal fistula, which was operated on about three weeks ago The abdomen was opened away from the fistula and a resection done, followed by lateral anastomosis The portion of the large intestine anastomosed was about the middle of the transverse colon The opinion of the pathologist who examined the specimen was that it was a congenital malformation, and that the atrophied ascending colon was the result of inflammatory trouble, probably of tuberculous origin Some rearrangement of the muscle fibres practically proved the condition to be congenital —Sir **JOHN LENTAIGNE** thought the origin of the trouble had been inflammatory in character, as many such cases were reported. He suggested that it had probably originated in or about the appendix. One of the reasons why he did not think this case was congenital was the fact that the girl had been well for 16 years He thought that if she had suffered from a congenital derangement to the extent shown in the specimen involving such a tight stricture she would have showed symptoms earlier —Dr **W M CROFTON** regretted that it was not known whether the abscess in the first instance was due to tubercle or other micro-organisms He suggested that the patient might have been saved a very severe operation if at the time the cause of the original abscess had been ascertained, and she was inoculated against it —Mr **KENNEDY**, in reply, said he did not look upon the atrophied ascending colon as congenital He only attributed the cæcum and absence of appendix to congenital defect As to the suggestion of saving the girl from operation, he thought it was beyond his power to render this abnormal intestine normal by any dose of vaccine The ileo cæcal valve was also abnormally narrow and would not permit a pencil to pass

Mr **A J MCA BLAYNEY** showed a number of small Stones removed from inside the capsule of the prostate There was a history of pain and frequency of micturition, and blood was said to have passed An attempt at cystoscopy had been made in America On a cystoscopic examination being made a tumour could be seen The patient stated that urine occasionally came through the rectum Per rectum a mass of the shape of the prostate could be felt somewhat like a stone The history, which extended back over ten years, was against malignancy A diagnosis of prostatic calculi was made and perineal operation was done, when the stones were removed from the prostatic urethra —Sir **JOHN LENTAIGNE** said the case was of importance on account of the occasional difficulty in diagnosis between malignant disease and this condition —Mr **C A BALL** said he had a somewhat similar specimen given him some years ago but the number of calculi and their size were larger, and the diagnosis was made by rectal examination as crepitus could be detected

Mr **BLAYNEY** related his experiences of an operation recommended by Patterson for the relief of Intestinal Stasis This operation consists of the removal of the cæcum ascending and part of the transverse colon The cases in which the operation was performed had as a rule suffered from marked ptosis of those parts of the intestine The operation had been done 21 times, with three deaths In those who survived there had been a very marked improvement —Mr HENRY STOKES discussed the question of sacrificing or saving the great omentum He thought Mr Blayney was to be complimented on the low mortality rate in these cases —Dr E M MAXWELL said she thought that the subject would become more important as time went on and methods became more exact She suggested that the primary focus of many things would be discovered, such as inflammations of the eye *She referred to one of the cases mentioned in* the paper A patient, aged 38, met with an accident to his eye, the day following she extracted a piece of iron, and he underwent a normal convalescence, but at the end of a year he returned with acute iritis of the right eye The patient informed her that during that year he was receiving treatment for constipation and dyspepsia, and about this time Mr Blayney resected a portion of the colon, and within five days the visual power was recovered, and within two months of the operation vision was as good as it had been before —Dr CROFTON said the operation was a very severe one and obviously, even in the most skilled hands, was attended by a very high mortality The cases that had recovered were undoubtedly much improved and taught important lessons Lane had shown the importance of the intestine, especially the large one, as a source of infection, but if it were possible to get the gastro-intestinal tract working without these operations it would be desirable to do so —Sir JOHN LENTAIGNE said if the value of this procedure was to be understood and the best means planned for treating these cases the causation of the trouble ought to be known The ideas generally held about it were very vague He thought a perfect elucidation had been given by Professor Combe, of Lausanne who had written two books on the subject, laying down in the plainest possible way, from his point of view the pathology and treatment of these conditions According to Combe the essence of the trouble in all these cases was the absorption of poisons from the large intestine produced by the decomposition of nitrogenous portions of food This bacterial decomposition of food occurred in every one, but in the normal individual there were safeguards by which it was checked and it was only when these barriers broke down that ill health ensued There were many other conditions which were produced by absorption of these poisons, and all of them at some time or other were amenable to medical treatment Great improvement could be brought about by diet but nevertheless many cases came to the surgeon sometimes owing to an acute attack and sometimes because they objected to restriction in diet or were too poor to be able to get suitable dieting or to face the long and tedious and more or less uncertain, medical treatment, and therefore had to be treated by a surgeon quickly It was therefore necessary that the best treatment should be ascertained What the surgeon saw when he opened the abdomen was probably the result of a very slow process which had gone on for years As to the operation Sir John Lentaigne considered that the best plan where the surgeon must interfere was to get a free emptying of the bowel and so relieve the stasis He was entirely in agreement with Lane as to complete removal of the colon but it was a very dangerous operation, and unless the technique was perfect the patient was very subject to sepsis Mr Blayney's operation, although it removed the worst part of the sink in which the putrefaction was going on left sufficient of the large intestine to cause further trouble He looked upon Mr Blayney's patients as likely to be improved but not cured —Mr BLAYNEY, in reply largely agreed with the remarks of Sir John Lentaigne as to the cause of the condition. The operation suggested by him was intended only for cases that could not be treated medicinally, and its object was to restore as far as possible the normal condition

ULSTER MEDICAL SOCIETY —At a meeting of the Society held on Jan 7th in the Medical Institute Belfast (Dr J S Morrow the President in the chair), Dr [illegible] read a paper on Diagnosis in Phthisis Dr [illegible] read Notes of a Case of Acute Intestinal Obstruction Caused by a Dermoid Cyst of the Ovary and Dr A Gardner Robb opened a discussion on the Present Outbreak of Scarlet Fever in Belfast —Interesting dis c[illegible] the reading of these communications

Reviews and Notices of Books.

On Pharmacotherapy and Preventive Inoculation applied to Pneumonia in the African Native, with a Discourse on the Logical Methods which ought to be Employed in the Evaluation of Therapeutic Agents

By Sir ALMROTH E WRIGHT M D Dub, F R S London Constable and Co 1914 Pp 124 Price 4s 6d net

THE lengthy title of this little book somewhat recalls the titles of the pamphlets which were at one time so much favoured by learned men, and the contents of its first part correspond to some extent with such a comparison, being largely logical and polemical in character The main thesis of this first part is the question of the value of æthylhydrocuprein hydrochlorate in the treatment of pneumonia, and certain experiments are set forth which were directed towards ascertaining the action of this substance on pneumococci in the presence of serum Unfortunately, the results obtained in human patients are disappointing, and the drug has some tendency to affect the optic nerve and cause blindness, it is in Wright's phraseology "optico neurotropic" The rest of the first part of the book is devoted to a discussion of the methods by which we arrive at truth in scientific medical investigation, and these are, according to the author, two—viz, the experiental and the statistical The latter is praised and practised by Professor Karl Pearson, who has thereby arrived at conclusions unfavourable to the value of the method of estimating the opsonic index of the serum devised by Wright This may perhaps explain to some extent the latter's apparent preference for the so called experiental method, which is a process of induction by the individual observer, based on his own experience, the value of the conclusions reached depending on the character of the observer and on his carrying out proper methods of research with due control experiments This is a little reminiscent of Aristotle's method of defining the virtues, each of which occupies a middle point between two vices, and this middle point is fixed "by reason and by the judgment of the practical man" It would seem that the practical man of one country—say, Germany—may differ from that of another—for instance, one of our own countrymen—as to the exact point where vice ends and virtue begins, and however immaterial this may be in the moral field it is inconvenient in science "Authority" will always have weight, but decision by authority hardly constitutes a valid scientific method At all events, the seeker for knowledge will be faced by the difficulty of determining who are the competent, and therefore authoritative, persons whose conclusions he can accept

The second part of the book is devoted to the question of the use of vaccines in the prophylaxis and treatment of pneumonia, the subjects of observation being the native labourers in a South African mine It seems that such natives are more susceptible to pneumococcal infection than are Europeans, that a considerable dose of vaccine—1000 millions or so—may have some prophylactic efficacy, but only for a brief period of time, and that while the administration of a vaccine during the incubative period of pneumonia may abort the attack, the use of this method in cases of the developed disease is of uncertain value Many other interesting points are incidentally recorded, Dr **HERBERT SPENCER** described a case of Extensive Cancer of the Cervix with Pyosalpinx, well seven years after Wertheim's hysterectomy The patient was aged 28 She had been examined by an obstetric physician, who advised her to go into a cancer ward as no operation could be done The cervix was occupied by a large ulcerated growth as big as a small apple, which distended the vagina The uterus was fixed by thickening in the left broad ligament and the left sacrouterine ligament, the thickening was not nodular Operation was performed at University College Hospital on Feb 16th, 1907 The cervical growth was first curetted and cauterised, and several protruding masses were cut off with scissors A solution of formalin (10 per cent) was then applied The operation was rendered difficult owing to the presence of bilateral pus tubes, which were adherent to the pelvis and rectum The separation of the left ureter was also difficult No glands were removed A small abdominal drain was used Urine escaped by the abdominal drainage tube for a few days and afterwards by the vagina The patient recovered and left for Canada, where a vesical fistula was found and closed by Dr Marlow, of Toronto Dr Spencer examined the patient every year for four years after operation and found no recurrence In a letter dated March 24th, 1914, the patient reported herself as in the best of health Dr Spencer did not think Wertheim's operation was as good as vaginal hysterectomy with the cautery for early cases of squamous carcinoma of the portio , but for extensive growths and for adeno carcinoma it was much better

Mr T G **STEVENS** described two cases of Hysterectomy for Ante partum Hæmorrhage The first was one of central placenta previa in a patient, aged 37 28 weeks advanced in her twelfth pregnancy She was admitted to Queen Charlotte's Hospital at 1 A M , having had a severe blood loss the evening before. The os uteri admitted two fingers and the whole lower uterine segment was covered by placenta as far as the finger could reach A de Ribes' bag was introduced above the placenta, considerable hæmorrhage occurring during the procedure Subcutaneous saline and morphia ¼ gr were given owing to signs of collapse Seven hours later the bag was expelled, the uterus was in a state of tonic contraction, and the cervix had closed up after allowing the bag to pass No further hæmorrhage occurred At this point Mr Stevens saw the patient and after debating the question as to the best method of delivering her, so as to avoid further blood loss, came to the conclusion that hysterectomy without opening the uterus offered the best solution As the child was already dead, this operation was performed under morphia atropine open ether anæsthesia, with infiltration of the abdominal wall by urea quinine hydrochloride Four pints of saline were infused subcutaneously The operation proved to be a very easy one, and was practically shockless The patient made an uninterrupted recovery The second case was one of external and concealed accidental hæmorrhage in a patient aged 33, about 30 weeks advanced in her ninth pregnancy She was admitted to Queen Charlotte's Hospital at 4 A M with the history of a big hæmorrhage at 10 P M the previous night. There was no hæmorrhage on admission, the pulse was 112-120, the patient looked very anæmic, and no placenta could be felt in the lower uterine segment The patient was kept quiet in bed, and 12 hours after admission bleeding recommenced An attempt to introduce a de Ribes' bag failed owing to the rigidly closed internal os Pituitary extract, ½ c c , and a little later morphia, ¼ gr , and 4 pints of saline were given subcutaneously, after which the external bleeding ceased The patient however, had a pulse of 150, and an examination of the uterus resulted in a provisional diagnosis of concealed hæmorrhage Seeing that the child was dead the internal os closed, and the patient in a very serious condition, Mr Stevens decided that hysterectomy without opening the uterus offered the best chance of saving the patient's life This was done under morphia atropine open ether anæsthesia with novocaine infiltration of the abdominal wall. Again the operation was very easy, and proved to be shockless the pulse falling from 150 to 134 at the end of the operation The patient made a good recovery The reason for the choice of hysterectomy rather than Cæsarean section in these two desperate cases was the impossibility of any guarantee that the latter operation could be done without further considerable blood loss Both patients had lost so much that a further loss of a pint would almost certainly have proved fatal Further, at the time that Mr Stevens saw the patients there was no possibility of delivery *per vias naturales* without a considerable loss The actual amount of blood lost during the operation in each case did not amount to three ounces, and under the method of anæsthesia chosen the operation was shockless

ROYAL ACADEMY OF MEDICINE IN IRELAND

SECTION OF SURGERY

Exhibition of Specimens —Intestinal Stasis

A MEETING of this section was held on Dec 11th, 1914, Sir **JOHN LENTAIGNE** being in the chair

Mr D **KENNEDY** exhibited a portion of Resected Intestine showing Congenital Absence of Cæcum and Appendix, with Atrophied Ascending Colon removed from a girl aged 20 Four years ago she had a subcostal abscess on the right side, which seemed to be shut off from the abdominal cavity The opinion formed was that it was a localised tuberculous abscess, and on opening it she made a good recovery Two years afterwards she developed a fæcal fistula, which was operated on about three weeks ago The abdomen was opened away from the fistula and a resection done followed by lateral anastomosis The portion of the large intestine anastomosed was about the middle of the transverse colon The opinion of the pathologist who examined the specimen was that it was a congenital malformation, and that the atrophied ascending colon was the result of inflammatory trouble, probably of tuberculous origin Some rearrangement of the muscle fibres practically proved the condition to be congenital —Sir **JOHN LENTAIGNE** thought the origin of the trouble had been inflammatory in character, as many such cases were reported. He suggested that it had probably originated in or about the appendix. One of the reasons why he did not think this case was congenital was the fact that the girl had been well for 16 years He thought that if she had suffered from a congenital derangement to the extent shown in the specimen involving such a tight stricture she would have showed symptoms earlier —Dr W M **CROFTON** regretted that it was not known whether the abscess in the first instance was due to tubercle or other micro-organisms He suggested that the patient might have been saved a very severe operation if at the time the cause of the original abscess had been ascertained, and she was inoculated against it —Mr **KENNEDY**, in reply, said he did not look upon the atrophied ascending colon as congenital He only attributed the cæcum and absence of appendix to congenital defect. As to the suggestion of saving the girl from operation, he thought it was beyond his power to render this abnormal intestine normal by any dose of vaccine The ileo-cæcal valve was also abnormally narrow and would not permit a pencil to pass

Mr A J McA **BLAYNEY** showed a number of small Stones removed from inside the capsule of the prostate There was a history of pain and frequency of micturition, and blood was said to have passed An attempt at cystoscopy had been made in America On a cystoscopic examination being made a tumour could be seen The patient stated that urine occasionally came through the rectum Per rectum a mass of the shape of the prostate could be felt, somewhat like a stone The history, which extended back over ten years, was against malignancy A diagnosis of prostatic calculi was made and perineal operation was done when the stones were removed from the prostatic urethra.—Sir **JOHN LENTAIGNE** said the case was of importance on account of the occasional difficulty in diagnosis between malignant disease and this condition.—Mr C A **BALL** said he had a somewhat similar specimen given him some years ago but the number of calculi and their size were larger, and the diagnosis was made by rectal examination as crepitus could be detected

Mr **BLAYNEY** related his experiences of an operation recommended by Patterson for the relief of Intestinal Stasis This operation consists of the removal of the cæcum ascending and part of the transverse colon. The cases in which the operation was performed had as a rule suffered from marked ptosis of those parts of the intestine The everyone who uses a work of this kind has to become more or less familiar with its characteristics before he can extract full benefit To take an example from the work under review, the references in the index are to paragraphs, not to pages A reader who gets accustomed to this method in a text book will find that it facilitates research, as he is brought straight to his subject without having to look for it through a possibly long and closely printed page Naturally, in a work devoted to the guidance of approved societies, only a limited portion of the contents touches upon the Insurance Act as affecting the medical man, a member of the panel, who apart from attending the patients on his lists has no interest in insurance A very large number of the medical profession, however, are concerned in administrative and organising duties, in performing which it is an advantage to have convenient and rapid access to the law upon a particular topic, especially when that law is largely contained in a rather confusing succession of orders and regulations This appears to be the first edition that Mr Willis has brought out, it is not issued so early that it need require immediate revision, but no doubt we shall see other editions follow in due course

Handbook of Obstetrics for Students and Junior Practitioners in India

By KEDARNATH DAS, M D, Teacher of Midwifery, Campbell Medical School, Obstetrician and Gynæcologist, Campbell Hospital, Calcutta. With 376 illustrations Calcutta Butterworth and Co 1914 Pp 612 Price 14*s* net

STUDENTS in India are to be congratulated on having at their disposal such an excellent text book as this The book is complete, accurate, and clearly written, and is evidently the work of a good teacher and practitioner In his recommendation to conduct a labour with as few vaginal examinations as possible the author is very sound, and his suggestion of estimating the progress of the head, after it has descended too deeply into the pelvis to be felt from above, by pressure through the perineum, is worth bearing in mind by the student We would suggest the great value of abdominal pressure in cases in which the birth of the body is delayed after the delivery of the head, it is free from the dangers which attend both traction on the head or the introduction of the finger into the axilla The plan followed by Dr Das, of leaving the breasts entirely alone when the mother is not to nurse her child is a sound one, and it deserves to be more widely practised than it is at the present time

The section on eclampsia is particularly good, and the author's statistics show very clearly how relatively frequent this disease is among natives of India The observation that in Bengalese only 5 5 to 5 8 grammes of urea are excreted per diem, as against 23 to 32 grammes in Europeans is a very interesting one The treatment of eclampsia is fully discussed, and the uselessness of the routine transfusion of saline fluid and the advantages of a solution of sugar, if the molecular concentration of the blood is raised, are pointed out At the same time it must be remembered that by most authorities the molecular concentration of the blood is held to be diminished and not increased In his account of hydatidiform mole the author does not mention the valuable observations of Briggs on the fact that the relative increase in the size of the uterus may be absent and that it may be even smaller than usual

The influence of Whitridge Williams's teaching is evident throughout the book, and Dr Das follows him in his neglect of the induction of premature labour as a means of treating cases of the medium degree of pelvic contraction, a view with which most obstetricians in this country would not agree In our opinion and in the best practice this operation is successful, and although it is true that the immediate fœtal mortality is high, yet the death rate during the first year of life is not much, if any, higher than that of children born at full term The methods of the Dublin school are not quite correctly represented in describing the treatment of accidental hæmorrhage According to Hastings Tweedy it is not necessary that "the ovum should be intact"—that is, the membranes unruptured—and he employs plugging the vagina successfully even after rupture of the membranes.

The book ends with a series of extremely valuable hints on obstetric surgery for the use of students These are marked by sound common sense and a clear recognition of the points upon which in teaching emphasis should be laid We repeat that this is a good book, and we congratulate the author on his success

A Manual of Minor Surgery and Bandaging (Heath Pollard) for the Use of House Surgeons, Dressers and Junior Practitioners

By H MORRISTON DAVIES M D, M C Cantab, F R C S Eng, Senior Assistant Surgeon in charge of beds and out patients University College Hospital, &c London J and A. Churchill 1914 Pp 467 Price 7*s* 6*d* net

Heath's 'Bandaging" was known to many generations of medical students in all parts of the world, the book before us is a reincarnation of that widely used work, and yet it retains enough of its original points to enable anyone who knew it before to identify it, even in its new form The general plan has not been changed, but several alterations have been made The chapter on poisons has been omitted, as the subject hardly comes within the scope of a surgical work, while the chapter on case taking has been replaced by one in which the general principles of the methods of examining a patient are laid down The chapter on anæsthetics has been revised by Dr Dudley Buxton and Dr Felix Rood, and the newer methods have been described Some indication of the many changes made may be gathered from the fact that nearly a hundred new illustrations have been added We are sure that this edition will meet with the welcome accorded to previous issues of the work

The Probation System

By CECIL LEESON Social Study Higher Diploma, Birmingham University, with an introduction by J H MUIRHEAD LL D, Professor of Mental and Moral Philosophy, Birmingham University London P S King and Son 1914 Pp 191 Price 3*s* 6*d* net

AN interesting result of the establishment of universities in the more important centres of English industrial life has been to stimulate in a remarkable degree the scientific investigation of the various social problems connected with modern urban conditions This has been shown in definite form by the organisation in several of the provincial schools of special departments of social study, to which sociological literature is already indebted for contributions considerable both in amount and quality Mr Cecil Leeson's monograph on the probation system is a creditable example of the work which is being done which we have not space to mention in a brief review. An appendix dealing with recent observations by others on the use of "optochin" (æthyl hydrocuprein hydrochloride) in pneumonia suggests that the danger of this remedy is less than was previously supposed, and that it is worthy of further trial on human patients.

The book is interesting and stimulating, as is most of its author's work.

Abwehrfermente.

Von EMIL ABDERHALDEN, Direktor der Physiologischen Instituts der Universität zu Halle a.S. Vierte bedeutend erweiterte Auflage, mit 55 Textfiguren und vier Tafeln. Berlin: Julius Springer. 1914. Pp. 404. Price 12 marks.

IT was only on May 16th last that we had occasion to review the third enlarged edition of this work on the "Defensive Ferments of the Animal Organism," as translated by Dr. J. O. Gavronsky and Mr. W. F. Lanchester. The first (1912) and second (1913) editions in the German text were reviewed in THE LANCET of Jan. 4th, 1913, and Nov. 8th, 1913. Now we have a fourth enlarged edition. These editions appear with almost bewildering activity. The third German edition is not before us, but we have compared the fourth German edition with the English translation of the third German edition. Substantially the text of the latest edition up to a certain point is much the same as the third. There are here and there omissions and addenda in the general text. In this edition the list of contents has been split up, so as to show more fully in detail the subjects dealt with, while in the text itself indications are given which enable the reader to see at a glance the subject under discussion, and the text itself is adapted in paragraph form accordingly. The author is far from thinking that he has attained finality in his researches; in fact, according to his statement in the preface, it is still impossible to give a final decision as to the practical value for the pathologists of the methods which he has employed.

Of the three additional plates the first one is coloured and shows the plumage of the bullfinch, which it appears has a testicle on one side and an ovary on the other. These animals "have on one side male and on the other female plumage, each being delineated accurately, and without any transition, along the middle line of the body." This subject is introduced as "a particularly fine example of the specific action of gland secretions upon cells of specific structure." The second plate is meant to show the method and result of the "ninhydrin" test and the biuret reaction, while the third shows the results obtained when a coloured substrate is acted on by the proteolytic ferments substrate present in serum.

In addition to what appears in the English edition, an account is given of the following questions and problems, some of which are new and which on account of their special importance are treated separately (pp. 139-204)—e.g., the employment of dialysation for determining blood free substrates in blood serum, the proof of dysharmonious substances by means of biological methods, "specificity" of the defensive ferments, the origin of the proteolytic ferments of blood plasma, the "inactivating" of dysharmonious ferments and their "reactivating" adsorption of dysharmonic ferments by the substrate, the application of the dialysis and optical methods in clinical problems and a criticism of the same, the carrying out of physiological and clinical experiments, and other cognate subjects. The chapter on methods has been added to and has been made more practical by the introduction of illustrations to show some of the more complex technical processes employed. The literature is brought approximately up to date, but there is no index. As if to bring the very latest results to the attention of the reader there is an addendum of a few pages.

As, according to the author, it will take many years of investigation to work out the problems herein presented, even this striking contribution to a weighty yet obscure problem can be regarded only as an instalment. We wish the author a successful continuance after the war is over in his persevering endeavours to illuminate a subject of great practical importance. An article in THE LANCET this week by Dr. Gavronsky, giving the results of clinical investigations based on Abderhalden's methods, will be read with interest, and will certainly tend to raise confidence in Abderhalden's work.

Cunningham's Manual of Practical Anatomy.

Revised and edited by ARTHUR ROBINSON, Professor of Anatomy in the University of Edinburgh. Sixth edition. Vol. II., Thorax, Head and Neck. With 267 illustrations in the text and 11 plates. London, Edinburgh, and Glasgow: Henry Frowde and Hodder and Stoughton. 1914. Pp. 636. Price 10s. 6d. net.

NEW editions of the "Manual" come fast, and this fact is in itself some guarantee that the subject matter is up to date. In this sixth edition the alterations are more considerable than a mere revision of the text, and we would especially call attention to the increased prominence given to radiographs of normal living bodies. The section dealing with the brain has been considerably altered, and many new and helpful illustrations have been added to this portion of the book. It is needless to say that the nomenclature of the Basle agreement—here called, with doubtful justification, "international" terminology—is retained in this, its real British godparent. We notice the incorporation of most that is new in the teaching of anatomy since the appearance of the last issue, and we congratulate the editor upon the perpetual virility of this widely used dissecting manual.

National Health Insurance through Approved Societies. Being a Practical Legal Treatise Incorporating the Operative Orders and Regulations.

By W. ADDINGTON WILLIS, LL.B. Lond., of the Inner Temple, Barrister-at-law. London: Published for the University of London Press by Hodder and Stoughton. 1914. Pp. xxx + 494. Price 10s. 6d. net.

THE title page summarises the objects for which this handy sized volume has been compiled, while the name of its author is a guarantee of lawyer-like qualities. Principally concerned, as it is, with the Insurance Act in relation to Approved Societies, it is likely to be found useful also by many who, in the exercise of their professions or officially, have to do with the practical carrying out of national insurance, and medical men, who as a rule have no time to gather information by hunting through statutes and regulations, will find Mr. Willis's methodical arrangements and lucid summaries of considerable assistance. Of course, experiments confirm the statement that the vagi both in the neck and in their branches contain not only secretory but also inhibitory fibres to the pancreas Secondary and inhibitory fibres are found equally in all branches of the vagus to the pancreas The secretion of pancreatic juice excited by the administration of secretin can also be inhibited by stimulation of the vagus Atropine in doses sufficient to paralyse the secretory fibres of the vagus does not paralyse the inhibitory ones —The Relation of Length to Tension Development and Heat Production on Contraction in Muscle, by C L Evans and A V Hill This communication is of interest to physiologists It has reference to isometric contraction —On the Ovarian Factor Concerned in the Recurrence of the Œstrous Cycle, by F H A Marshall and J G Runciman The authors have investigated the problem as to what part of the ovary is responsible or mainly responsible for the recurrence of the procestrum and œstrus in the dog in which the cycle is very regular, and in typical cases extends over about six months The animals were operated on about three weeks before a new heat period was due The ovaries were exposed, at least nine enlarged Graafian follicles were pricked The animals rapidly recovered, and three weeks later manifested what seemed the normal phenomena of heat The animals were killed a week later and the ovaries examined microscopically The experiments show that the occurrence of "heat' in dogs does not depend upon the presence of mature (or nearly mature) Graafian follicles in the ovaries, nor upon corpora lutea, so that some other ovarian element or combination of elements is the cause The ovarian interstitial cells are possibly concerned in the process, but cyclical changes in the condition of these cells have not so far been observed in the dog s ovaries The view that the ripening of the Graafian follicles and the onset of menstruation or heat stand to one another in the relations of cause to effect must be abandoned —Fatty Metabolism in the Liver III Fatty Acid Infiltration of the Liver during Pregnancy and Lactation, by R. Coope and V H Mottram In rabbits dieted for a month a decided increase in the fat of the liver was found to occur at, or about the time of parturition so that this fatty infiltration of the liver is a physiological and not a pathological process —The Afferent Fibres of the Abdominal Vagus in the Rabbit and Cat by K O Neuman — Some Results of Excision of the Adrenal Glands by T R Elliott The observations were made on the cat, an animal which invariably dies after excision of its glands The author s purpose was to analyse the manner of this death, and especially to see whether the end comes with a general failure of the nerve and muscle machinery of the sympathetic nervous system inasmuch as the medulla of the gland is so closely related with that system of nerves After removal of both glands death usually takes place on the second day Removal of one adrenal gland in a cat does not obviously affect the animal s health nor does it when in addition the splanchnic nerves on the opposite side are cut It causes usually some hypertrophy of the remaining adrenal and of accessory adrenals more especially, if not almost entirely of the cortical tissue Subsequent removal of the remaining gland practically always causes death but death does not occur so quickly as when the two glands are removed at one operation In the moribund cat the blood pressure is low and there is nearly complete paralysis of vasomotor and cardio-accelerator nerves (all other nerves reacting in an appropriately normal manner) The paralysis is due to a change in the unstriated muscle since pituitary extract and barium chloride have little or no effect while adrenalin still causes a rise of blood pressure and a quickening of the heart beat The paralysis of the vasomotor nerves is not due to shock The paralysis is due to the absence of adrenal secretion Some evidence is given that the cortical adrenal cells influence sex characters —The Relation between Successive Responses of the Ventricle to Electric Stimuli and Ventricular Fibrillation by A G Levy The general direction of the observations is to support the view suggested by Mines that a circulating rhythm underlies the conditions known as ventricular fibrillation —The Respiratory Exchanges of the Heart in the Diabetic Animal by E H Starling and C Lovatt Evans Many researches on diabetes have shown that the respiratory quotient (R Q) in intact diabetic animals is low compared with that of the normal animal and similar results have been obtained on surviving excised organs The author s observations were made on the heart-lung preparation of the dog It was found that the average R Q for the normal dog's heart is 0 85 The heart uses 3 2 c c oxygen per gramme per hour when doing moderate work, and about 1 6 mg of carbohydrate per gramme per hour when the animal is fed on a mixed diet The lung tissue per gramme of heart uses not more than 0 5 mg of sugar per hour as calculated from the gaseous exchanges The R Q of the diabetic heart in pancreatic diabetes is about 0 71, due partly to the inability of diabetic tissue to utilise carbohydrate, though there are perhaps other factors The average oxygen usage of the diabetic heart is 3 1 c c per gramme per hour, from which it is inferred that the energy requirement of the diabetic tissue is the same as that of the normal one — The Estimation of Non protein Nitrogen and Urea Nitrogen in Blood, by Charles G L. Wolf This communication is of interest to biological chemists, and hangs in connexion with the following communication The Metabolism of the Salivary Gland I, The Nitrogen Metabolism of the Resting Gland, by Charles G L Wolf and Joseph Barcroft This, like the previous paper will be specially interesting to biological chemists, and is an attempt to investigate the nitrogenous metabolism of the submaxillary gland by direct methods, a sharp distinction being drawn between (1) protein and (2) non protein nitrogen

Archives of the Roentgen Ray —The December number opens with a valedictory note from the editor Mr W Deane Butcher who for reasons connected with his health finds it necessary "to abandon a task which for many years has been for him a labour of love." Every radiologist and probably many others will receive this announcement with the greatest regret coupled with the hope that Mr Butcher may be spared for many years yet to watch the progress of the science he has done so much to foster and encourage Only those who have had the privilege of coöperating with him have any idea of the immense amount of work he put into the *Archives* and not the least important part was his regular attendance at congresses at home and abroad, where his kind and friendly disposition and his scientific enthusiasm made him one of the most respected and popular members present This last number of the *Archives* to be issued under Mr Butcher s direction well maintains the high standard set by him from the time he first took charge The excellent series of articles on Diathermy is continued by Dr E P Cumberbatch This series, when completed, might well be published in book form as the subject is one that is commanding increasing attention Most medical journals have something to say about bullet wounds at the present time and we have here a method of localising bullets by Dr F Hernaman-Johnson, with a letter on the same subject by Mr C Thurstan Holland Dr Arthur F Hertz contributes a paper on the X Ray Diagnosis of Gastro-Intestinal Conditions, with special reference to Appendicitis, in which he points out that in quite 50 per cent of cases the appendix can be seen if carefully looked for, and many important conditions accurately diagnosed Dr J MacIntyre, of Glasgow discusses the comparative value of X rays and radium in the treatment of malignant growths—a question that is rapidly coming to the front With the very powerful apparatus now available and the use of screens to shut off the rays that were so prone to set up X ray dermatitis massive doses are now possible that were undreamt of a few years ago, with results that are eminently satisfactory —In the present issue (January, 1915) of the same journal we have the first number to appear under the new editorship, which is now of a three-fold character Dr Robert Knox, radiologist to King s College Hospital Dr E P Cumberbatch of the Electrical Department at St Bartholomew s Hospital, and Dr Sydney Russ physicist to the Middlesex Hospital have now taken over the charge of the *Archives*, a selection that augurs well for the future We note with pleasure that the name of the late editor appears among the list of the collaborators Some important experiments bearing on the question of X ray filtration and dosage are contributed by Dr J H Sequeira A paper dealing with bullet wounds by Dr A J Cleveland describes a modification of the Mackenzie Davidson method of localisation, while Mr Gilbert S Scott shows two plates illustrating some effects of the modern bullet The notes and abstracts as well as the other special features of this valuable journal, are very complete and useful under these influences It deals with a reformatory method which has come very much into favour in this country and in America as a result of the general recognition that the old-fashioned panacea of imprisonment is usually ineffective, if not positively mischievous, as a means of correcting criminal tendencies, and that recourse should be had to so extreme and *dangerous a remedy only* when every other way has been tried and found inadequate Under the probation system offenders, instead of being sent to gaol, are conditionally released *under the friendly* super vision of a skilled social worker, known as a probation officer The system has been widely applied in the United States since 1878, both to juvenile and to adult offenders, and it received full legislative sanction in England by the Probation of Offenders Act, 1907 Mr Leeson gives a clear and concise account of the principles of the method, and discusses its *merits and defects in an eminently* temperate and reasonable spirit It is satisfactory to note that he fully recognises the importance of skilled inquiry into the mental condition of persons whom it is proposed to put under probation It is a method which is obviously useless in the case of mental defectives, and many of the failures which have exposed it to hostile criticism have been due *to the error of applying it to weak minded* delinquents for whom life long control is the only rational mode of treatment Mr Leeson's book is altogether a very creditable piece of work, and may be commended to the attention of readers who desire to learn something of one of the most promising developments in preventive criminology

MISCELLANEOUS VOLUMES

Our Miscellaneous column this week fully lives up to its name, *covering as it does popular* philosophy, travel, war, and linguistics

In the form of a dialogue, one of the speakers being a charming woman "once a swimming reptile," as she is informed, Mr H De Vere Stacpoole in *The New Optimism* (London John Lane 1914 Pp 42 Price 3*s* 6*d* net), epitomises the story of evolution, with the object of showing that the world has a meaning and life an aim that side by side with the building up of forms there is a building up of character and a "*progression towards the benign*" Whether or not we accept the conclusions which the book presents to us, "The New *Optimism" is intellectually stimulating*

A Woman in China (London T Werner Laurie, Limited Pp 890 Price 15*s*) by Mary Gaunt, a great traveller, is written in the bright, breezy, discursive style that characterised her book "Alone in West Africa' It gives a picture of China and things Chinese under the modern conditions of the new republic which will be of interest not only to those to whom far Cathay is quite unknown, but also to those whose *previous conceptions* are based on a *personal* experience of some decades ago It contains little of any special *medical interest, though in* Chapter XIV the amateur medical services of the devoted missionary (not a medical man) and his wife at Jehol aided by a German girl who was a certificated midwife are briefly depicted with a sympathetic touch The book is elaborately illustrated by the author s own photographs, 130 in number which greatly enhance its interest

Chinese Self Taught by the Natural Method, with Phonetic Pronunciation (Thimm s System) by John Darroch Litt D (London E Marlborough and Co 1914 Pp 153 Price wrapper 4*s*, cloth 5*s*) is designed to serve the double purpose of a text book for students officers, civil servants, missionaries and such like, and a handbook for tourists travellers and other temporary visitors to China with the exception, perhaps of the southern ports and Hong Kong Canton, Amoy, and Foochow where *no spoken* phrase from the book is likely to be understood Each of these places has a totally *different* dialect *from* its neighbours and this book professes to set out only the Mandarin or official language " which, *it is claimed*, is spoken by seven eighths of the population, with, of course local variations It is up to date, as we *observe that the* Red Cross Society is phonetically represented as "Hung shirr dz hway," and the Chinese *ideograph for it seems* to a western eye to look like a lamp post shedding its beams, followed by a dumb bell, a St George s cross, an old open umbrella with a skewer through the handle, and a little gable ended cottage We notice that the doctor (army) is "ee sung ' but in another place he is called "bo siz " and he is probably a civilian as he comes next to the fisherman and farmer, but then the physician is also "ee sung,' and the *surgeon is* "wi ko ee sung " The dentist is ' yah ee sung ' and turning to the 'human body" list *we see that "ya chirr"* are teeth The mouth is "kou " and the ideograph is nothing but a simple square The heart is "sin " and a servant is a "yung run," and there are other indications in the *vocabulary suggesting* that it might be possible for a man to teach himself some sort of Chinese, though we imagine his knowledge would not take him far — Another book of the same series is *French Self Taught by the Natural Method with Phonetic Pronunciation (Thimm s System)*, by J Lafitte (London E Marlborough and Co 1914 Pp 148 Price, paper 1*s*, cloth, 1*s* 6*d*) a second edition of which is now out We have expressed *our opinion* in reviewing the first edition on the in our opinion, invincible *difficulties inherent in any* "phonetic" attempts to convey accurately pronunciation by the eye, but at the present juncture, when all that is required by many is to make themselves intelligible the book may prove of service, instruction by word of mouth being often impracticable.

The Nightside of Japan (London T Werner Laurie Limited 1914 Pp 233 Price 7*s* 6*d* net), by T Fujimoto, is a quaint description by a Japanese *for Europeans of* native life and customs in modern Japan Theatres, hotels, railway travelling, *public* baths, *the temples the Geisha* girls the Yoshiwara and various types of Japanese are graphically described Noticeable features from a point more nearly concerning the medical man are the sections on bathing and massage In Japan massage is quite an occupation for the blind There is a piquant attractiveness in the quaint English of the author, and we think the publishers acted wisely in refraining from having the manuscript corrected by a literary man, who would probably have dissipated the peculiar atmosphere of the book

Fighting in Flanders (London William Heinemann 1914 Pp 231 Price 3*s* 6*d* net), by Mr R Alexander Powell, is a vivid and graphic narrative of what the author *saw* in the area of war from its beginning up to the *fall of Antwerp* It is told with a racy humour, expanding in *places* into broad farce such as one has become familiar with at the hands of the American journalist, then again contracting with all the tenseness of tragedy as the deeper tones are sounded As one reads the narrative it becomes easy to understand the conversion of the author—an American, as he describes himself who went to Belgium with an open mind, knowing the English, the French, the Belgians and the Germans equally well and having friends in and *happy* memories of each of the four nations—into a "pro Belgian " The numerous photographs by Mr *Donald Thompson add greatly to the* interest of the book

JOURNALS AND MAGAZINES

The Journal of Physiology Edited by J N Langley, Sc.D F R S Vol XLIX Nos 1 and 2. Cambridge University Press 1914 Price 7*s*—The Influence of the Vagus on Pancreatic Secretion by G von Anrep In 1888 Pawlow asserted the existence in the vagi of *secretory* fibres for the pancreas and later in the splanchnics, and fibres in the vagus which diminish or abolish *secretion* With the discovery of secretin in 1902 some began to doubt the accuracy of Pawlow s observations, while the Popielski *school held that all the phenomena* are to be explained by a nervous mechanism The author in Pawlow s laboratory *has reinvestigated the subject* in dogs anæsthetised with chloroform and ether as morphia injuriously affects the vagus fibres *The spinal* cord must be completely and quickly cut and the bulb must not be crushed Vagus stimulation yields no secretion when the spinal cord is undivided Why this is so is not known Tracheotomy was performed the œsophagus tied in the neck, a cannula placed in the duct, and the vagi exposed as they run along the œsophagus, so that they *could* be stimulated either in the neck or in the chest. The

THE LANCET.

LONDON SATURDAY, JANUARY 16 1915

The Coördinated Study of Gunshot Fractures

THE conditions of the present war are quite unprecedented Not only is the number of our men actually fighting at one time greater than it has ever been before, but there is a correspondingly large proportion of the medical men of the country engaged in attending upon the wounded Again, the fields of battle are many of them so close that an effort can be made to send the wounded back to this country quickly Yet even the nearest battle field is so far off that such transport, involving, as it does, the placing of the wounded on and removing them from ships, is fraught with both great difficulty and danger. In order to utilise as far as possible the services of medical practitioners at home there have been formed large general military hospitals in the British Isles, and to these the wounded are being sent either directly or after a longer or shorter period of treatment in one of the base hospitals in France The scheme of organisatión has been described in our columns, and is familiar to all our readers, who will see that a wounded man may have to go to a field hospital, a stationary hospital, a base hospital, a general hospital, and subsidiary hospital in the course of his journey to recovery, or may skip any link in the chain in accordance with circumstances personal to himself or arising out of the exigencies of warfare

The system is probably the best that can be devised in all the circumstances, it is the outcome of much thought and practical experience and is working well on the whole and splendidly in some directions But in order that it may produce the best results it is desirable that a very close understanding should exist between those responsible for treatment of the patient in his various stages, so that a right course of therapeutics if started, should be *maintained*, and any emendations decided upon should have the best chance of success These remarks apply with especial force to the treatment of severe gunshot fractures With regard to these the march of surgery has been in advance of all practical military experience When last we were engaged in war on a large scale near home, the rule applied that all severe gunshot injuries of the limbs with open fractures of the bones must be amputated at once, for then the results of primary amputation were far superior to those of secondary amputation. It is now the ambition of modern surgery to save the majority of these limbs, and this ambition is happily fulfilled in many cases But unfortunately in the attempts at conservatism lives are lost and limbs are saved in a useless condition through the endeavour to secure more perfect results than those of immediate amputation Things were much simpler in the old days A shattered limb was amputated on the field or at the base, and if the patient recovered there was little or nothing further to be done for him on his return home During the Napoleonic wars our countryside was dotted with our luckless defenders, who, one armed or one legged, were too often compelled to look to charity for their subsistence We shall not see this sad and discreditable spectacle again, but now, with the problems of treatment and the machinery for their solution far more complex, new difficulties arise It is the responsibility of modern surgery to meet these difficulties thoroughly and scientifically Take, for example, the case of a man with an open comminuted fracture of the femur, the injury received in a muddy trench. First he has to be dressed on the field or in the field ambulance, then he has to be transferred to a place of safety, the leg for the time being immobilised At last—and the amount of delay must depend upon the general conditions of the fighting in the area—he reaches the base hospital, where his case can for the first time be fully treated The wounds, fairly certain to be septic, demand immediate attention They are opened up and a number of fragments of bone are found lying in their depths Ought these to be removed or to be conserved as far as possible? No general rule of treatment has so far been formulated This question is answered very differently by different surgeons, although the conditions must in the majority of instances be similar In the less severe type of case sepsis may not be so virulent, nor the bone so much splintered But here the following doubts arise Is it wise to leave the bones alone? Is it better to allow the soft parts to remain lax and the bone ends overlapping? Or should extension be applied from the first? If the fracture is clearly exposed in the wound some surgeons may prefer to fix the fragments, by nails, screws, wires, or plates Indeed, to every one of these questions there are different answers, and accordingly different practices Some surgeons remove all loose bone fragments, others leave them in place, others only remove those fragments which are devoid of attachments and others again, it is said, take out fragments, wash and replace them Some adopt continuous extension of the limb from the outset Some do this in a straight position whilst others maintain the semi flexion of the joints

THE FLOODS AND PUBLIC HEALTH

(FROM OUR SPECIAL SANITARY COMMISSIONER)

THE floods affecting, not only the Thames valley, but many other parts of the country will tax the resourcefulness of our sanitary authorities to the utmost The dampness caused by the water that invades dwelling houses is, of course, unwholesome, but the specific contamination due to the filth floating in the water may be more dangerous In spite of great sanitary progress, no system of drainage has been devised that can protect dwellings from sewage if the floods reach a sufficiently high level The water in the sewers, of course, can only carry the sewage away when the outfall is at a lower level than the sewers, save where the conditions warrant elaborate pumping or exhaustion schemes On the water rising at the outfall it penetrates the sewers, and the first thing that happens is the forcing back of a large volume of sewer air If the sewers are not well ventilated at frequent intervals the sewer air pressed backwards by the rising flood will break the seal of the domestic drains and invade the dwelling rooms of the houses The actual toxicity of sewer air is not now in question—anyhow, no one wants it in the house If the water rises higher still the sewage itself overflows from the street and yard gullies or sewer mouths If there are closets in the basement of the houses the sewage will come out of them into the house If the closets in the house are above the level reached by the flood there will of course be no overflow from the closet, but the lower portions of the soil pipe connecting with the sewer in the street may not be strong enough to resist the unusual pressure The drain pipe may then burst, and then the sewage may be distributed alike upon the streets and inside the houses

The Floods and the Sewage Disposal Works

Even where the flood is not so extensive as to produce an extreme effect it is very likely to invade the sewage disposal works for these must be at a very low level, and this means frequently proximity to a water course This is not a matter which need unduly frighten us It has been calculated that the sewage from a total population of one and a quarter million people, living in the Thames valley, ultimately reaches the Thames above the intake of the London water supply Yet few, if any, cities enjoy so pure and safe a water supply as London The sewage in the Thames valley is carefully treated and purified before it is allowed to flow into the Thames, while the London water supply is kept safe by the efficient methods of storage and filtration employed

The chief concern in London, of course, is the protection of the water supply from the floods In 1894 after severe floods, there was a considerable amount of typhoid fever in London But since that date the water supply, especially the storage of the water has been greatly improved The water reservoirs are now of such vast dimensions that the water may remain standing for a very long time before it is drawn off for use This prolonged settling process, apart from filtering, greatly facilitates purification There is no reason to fear in London that the flood waters will be mixed with the drinking water The storage is so enormous that the intake of Thames water can be stopped for a while London is drinking Thames water now which was collected before the floods It is to be hoped the stored supply is sufficient to meet all wants till the floods are over but the rainfall has been a very exceptional one and the floods have prevailed for some time When the great reservoir was built at Staines complaints were made that its embankments were so lofty that they blocked out the view and spoilt the scenery of the surrounding country Now that the floods are carrying away the contents of privies and distributing broadcast the filth from neighbouring sewage works we may be thankful that these embankments are too lofty for the floods to flow over them and contaminate the store of drinking water for London

When a flood invades sewage works it swamps the filter beds and scatters the untreated sewage in all directions After the floods have subsided the neighbouring fields are found to be covered with a thick and odoriferous layer of sewage sludge The whole system of sewage disposal has become inoperative, and the only hope is that the immense volume of water produced by the flood will suffice to purify the foul matter it carries away In the swollen river, in streets that have become small rivers, there may be a current, and a sufficiently rapid current, to wash away decomposing matter But inside a house, confined within the four walls of a basement or a cellar there is no current. The water stagnates and deposits filth on the walls and floors as it gradually subsides

The Contamination of Dwellings by Floods

In many flooded districts especially among rural populations, there are no sewers Even in comparatively large provincial places it will often be found that the water carriage system is only applied to the more favoured parts of the town There are still provincial towns of some size where, as well as water closets, there are cesspools, privy middens, or pails The cesspools are emptied by night-soil men once a year or oftener, while the pails are generally removed once a week When a flood occurs in such a place the soil, of course, mixes with the water and floats away from the pails or privies, is carried all over the inundated district, into the houses, and into the wells Thus water and dwellings are contaminated All these risks are now with us over a large area and in some districts are aggravated by the large number of camps for the training of the Territorials and other troops We know how severe the floods have been at Salisbury It is to be hoped that the latrines for the soldiers encamped in the neighbourhood are constructed according to the most approved principles, but even so, no system has been invented that will prevent a flood lifting out the contents of a latrine and scattering it about A reasonable step would be to remove the camp to a district out of reach of the flood—a very practical object-lesson in military training, for when the enemy discovers the right range their shells come more rapidly than a flood Then there is other dangerous matter besides the contents of sewers or cesspits Apart from waste products coming from yards where skins are tanned, tripe prepared, offal dealt with, and many other unpleasant and unwholesome industries carried on, there is the vast accumulation of household refuse, the contents of our dust bins That, again, is scattered in all directions and brought inside our houses by the invading floods

Remedial Measures

From all this there results the obvious necessity of applying very prompt and vigorous measures for cleansing and disinfecting the portions of the houses that have been submerged This, indeed must be extended to all parts of the buildings where the damp has extended, even though it may be some distance above the highest water level To give time for this to be properly done, it is fortunate if the waters subside gradually, as all the dwellings cannot be treated at one and the same moment When the floods are beginning to go down, disinfectants notably chlorinated lime, in suitable quantities should be thrown into the water that remains in the basements or cellars There it should mix with the sludge or mud deposited by the water on the walls and on the floor The mud should be piled up in some open space and sprinkled over with a disinfectant The walls, floor, and ceiling of flooded rooms or cellars will require very careful washing and scrubbing, and finally should be thoroughly whitewashed A flood provides an excellent opportunity for a general clearing Rubbish and lumber that may have accumulated during years in cellars or under staircases and basements is rarely worth saving, and can now be very advantageously destroyed, burnt if possible Bedding if it has been soaked in suspect water, should not be spared unless it be of such very good quality as to warrant incurring the expense of thorough disinfection Such cleaning work requires strict supervision It is questionable whether all the sanitary authorities concerned have at their disposal numerous staffs to ensure that efficient measures will be taken This is an occasion when the county medical officers of health may have to exercise their right of supervision over the smaller district sanitary authorities The cleansing of flooded houses must be well done everywhere and not strictly enforced in one locality and neglected in another plan. The second object of the Fund is the assistance of Belgian doctors and pharmacists who are refugees in this country. A large number of Belgian doctors and pharmacists are with us whose needs are urgent. Some had little or no opportunity to bring any money with them, many can obtain nothing to supplement what they brought with them, and the duration of the war will be such that any supply of money brought over by them from Belgium will be exhausted in most instances before they can return to their country to resume professional work. The Fund, out of subscriptions received and acknowledged in the medical journals, has given assistance already to certain of these refugees. A small subcommittee has been empowered to make grants of money in suitable cases, and for this purpose takes the advice of the President of the Belgian Society of Medicine in London, who personally communicates to the honorary officers of the Fund the details of the cases where assistance is required. Thus in two directions already the comparatively small sum of money as yet raised is being utilised, and in both directions it is clear that more money will be required. We have reason to believe that owing to active coöperation in the United States the difficulties attendant upon sending parcels of drugs into Belgium will be minimised, when at once large stocks of medical material should be obtained and shipped. Moreover, the medical refugees in this country are likely, as time goes on, to require more and more succour. There are, therefore, immediate uses for any money subscribed to the Fund, and real need for many more subscriptions.

But there will be a further employment for such money later. Not only is it certain that more money will be wanted in the two directions where action is already possible, but it must be remembered that it has always been the ideal of the Fund to obtain money for the assistance of Belgian doctors and pharmacists when that gallant country is free from invaders, and is making efforts, with the world-wide assistance which she will obtain, to recover from the horrible plight to which German ambition has reduced her. All nations save three will rush to the aid of Belgium when the time of her rehabilitation comes, and two of her three enemies will, it is our confident belief, be compelled to subscribe to the same object. It is the hope of the committee of the Belgian Doctors and Pharmacists Relief Fund to gather together a substantial sum of money, and to coöperate with similar bodies throughout the rest of the civilised world in an international movement. This is the second use to which subscriptions will be put.

LITERARY INTELLIGENCE.—Messrs. Cassell and Co., Limited, announce for immediate publication the fifth edition of Luff and Candy's Manual of Chemistry, revised and enlarged by Mr. Candy. Much of the additional [illegible] refers to the theory of ionisation and some of its [illegible]. The section on volumetric analysis has now been extended to include the volumetric aqueous solutions of the [illegible] Pharmacopœia.

Annotations.

"Ne quid nimis."

THE REGULATION OF THE HEART BEAT.

THE "heart-lung preparation" of Knowlton and Starling has now obtained a permanent place in physiological research. By means of it the mechanical performance of the mammalian heart can be accurately studied, and clearer ideas of its capacity for work and its power of adapting its work to the mechanical conditions imposed upon it obtained. The latest experiments of Patterson, Piper, and Starling show that it is difficult to imagine a more perfectly regulated machine than the heart.[1] Leaving aside such regulatory factors as the influence of possible chemical factors and nerves in the intact body, it is plain that the heart-lung preparation is free from all nervous control, so that the question arises whether we can refer to one or a few elementary qualities of the muscular tissue the whole behaviour of the heart "under stress or light work, when efficient or failing, when stimulated or depressed by drug or nerve." This is the interesting problem which has occupied the attention of the above-named observers for the last two years. Their results are most interesting, as well as of great practical importance. The behaviour of the heart must be the sum of the behaviour of its constituent muscle fibres. It is interesting to compare its inner activity with that of skeletal muscle. In a skeletal muscle it is found that the longer the muscle the greater is the amount of chemical energy, heat production, and tension set up when the muscle passes from the resting to the active condition—results which also obtain in cardiac muscle, making allowance for the different arrangement of the heart fibres, and the fact that the heart contracts rapidly and rhythmically, so that both the tension and length of its fibres alter continuously during diastole from one beat to the next. E. H. Weber originally stated that a skeletal muscle during contraction changes into a body with other elastic properties, or, as recently expressed by A. V. Hill, excitation causes a setting up of a new state in muscle. At and after this moment the muscle is simply a new elastic body of changed elastic properties and possessing potential energy which can be turned into work if we desire, but which otherwise will degenerate in a few hundredths of a second into heat. Neither the length nor the tension of the heart fibres can be measured directly, but on the length of the fibres depends the capacity or volume of the heart, while the tension of the muscle fibres determines the intracardiac pressure. Professor Starling and his colleagues therefore adopted methods to determine these factors during rest and activity of the heart. It is found that the "law of the heart" is the same as that of skeletal muscle. The mechanical energy set free on passage from the resting to the contracted state depends on the area of "chemically active surfaces"—i.e., on the length of the muscle fibres. They claim that this simple formula "serves to explain the whole behaviour of the isolated mammalian heart—its movements, powers of adaptation to varying demands made upon it, its

[1] Journal of Physiology, [illegible] xlviii, [illegible] THE LANCET, Nov. 7th, [illegible] p. [illegible]

We do not here advocate one method of treatment rather than another, and in any particular case he would be a rash person who should attempt to dogmatise, but we would point out that of all these various practices some must be right and others wrong when applied over a long series of cases having many qualities in common. It ought not to be merely a question of personal opinion or of text book rule, for we may say that no opinion and no text book can speak with authority under the peculiar circumstances of the present war. It is clear that we must be prepared to regard ourselves, as a nation, as only at the beginning of the war, and it ought to be possible at this early stage to collect a body of evidence about all these points which should in the main serve as a guide for practice in the immediate future. Take two only of the debated questions. First, ought fragments of bone to be removed from open septic comminuted fractures? We think the usual answer is in the affirmative, but patients arrive in this country with great gaps in the continuity of the large bones, which will have to be made good by difficult and tedious bone grafting at a later date, if indeed anything can be done, when very great loss has occurred. If, on the other hand, the bone fragments might safely have been left and it could be shown by a series of cases that they afterwards unite to reconstitute the broken shaft, then all workers would be in a position to benefit by this fact. Secondly, ought the fragments to be fixed by plates and screws in a septic wound? If this can be done with impunity then there is a great gain in time, saving of pain, and facility of transport. But this bold and unorthodox plating may produce disastrous results, under which the patient arrives at the general hospital with his leg firm and straight, but subsequently the whole length of the plated bone necroses and leaves a huge gap. What is to be said in such circumstances, and who is to say it? One surgeon takes out the bone fragments and another is left to deal with the flail like limb. One surgeon screws on plates and another has to make the best of the resulting destruction of bone. At the end of the war no doubt we shall be supplied with masses of statistics justifying different procedures, and some may think that this recorded experience should be awaited, saying that the present is not the time to write but to act. But the end of the war will be too late for thousands of maimed soldiers. Surely it is desirable and possible to institute some system of coöperative effort, first in the registration of facts, and then in the carrying out of principles, so that surgeons at the field hospitals, base hospitals, and general hospitals shall be able to unite in carrying out a well approved system. Any practice in an early stage which gives bad final results could be noted and checked, and the discovery of any new treatment or appliance should quickly be placed at the disposal of all.

Our Belgian Colleagues

WE publish this week a circular which has gone out in many directions to medical practitioners explaining the objects of the Belgian Doctors and Pharmacists' Relief Fund, which is being raised to organise assistance, in money and in kind, for Belgian medical men and pharmacists, both those remaining in Belgium and those who are refugees in this country. The information in the circular has all been published in different issues of the *British Medical Journal* and THE LANCET, but the time has now arrived when a consecutive story may be told with advantage, for it is difficult for anyone who is not actually concerned in the details of a movement to follow its progress from week to week. We want our readers to understand clearly both what the promoters of the Fund have before them as objects, and in what directions they have so far been able to work, for upon such understanding further support will follow.

It may be pointed out that the aims of the Fund are twofold, and that the uses to which it is proposed to put any money collected are also twofold. The terrible position of the country of Belgium—submitting, save in one tiny strip of territory, to the occupation of the Germans—has dictated both the objects of the Fund and the methods of its distribution. First, with regard to the objects, Belgian doctors and pharmacists who are remaining in their own country—and these comprise, of course, the great majority of both professions—are in the midst of a population in the most dire need of their ministrations, but to a great extent they are unable to play their professional parts. They must look on while the people die, especially the children, to whom the Belgians look to replace in due time the gaps in their depleted numbers. The devastation of war has left both medical men and pharmacists largely without money, often without houses, and, as we learn from authoritative sources, quite without any of the material with which to render actual therapeutic assistance. These pharmacists and doctors are alike in recognising that in most instances their unfortunate countrymen cannot be expected to pay fees, but even were fees obtainable the tragic situation would be the same, for medical assistance is usually of little worth in the absence of drugs, dressings, and instruments. Thus the earliest object of the Fund was to try to establish communication with the Belgian doctors and pharmacists in Belgium so that they might be supplied with drugs and instruments. How far this will be possible with any regularity or in any bulk cannot be said, but the Executive Committee of the Fund, having obtained the invaluable sympathy of the American Ambassador in London with the endeavour to create a channel of supply, is now acting through the International Commission for Relief in Belgium, and hopes soon to be able to transmit medical material to Belgian doctors and pharmacists upon some regular amount of this water must reach the reservoirs The well known purifying process of sedimentation by storage would obviously occupy a much longer time for completion in order to bring the water to a sufficiently pure state for drinking purposes It is to be hoped, however, that the increased vigilance which would seem imperative at a time when a great flow of storm water occurs, with its heavy charge of impurities drawn from the land, will be exercised by our authorities. It will be interesting in any case to watch the future official reports upon the purity of the supply based upon the examination of samples synchronising with the flooding period The precautions alluded to apply equally of course, to other parts of the country which derive their water supplies from rivers, for the excessive rainfall was general

MEDICAL RECIPROCITY WITH BELGIUM

BY an Order in Council published in the *London Gazette* of Jan. 8th it is enacted that, "whereas the Kingdom of Belgium affords in his Majesty's opinion to the registered medical practitioners of the United Kingdom such privileges of practising in Belgium as to his Majesty seems just, during the continuance of the present war, now, therefore, his Majesty doth hereby, by and with the advice of his Privy Council, order, direct, and declare that the Second Part of the Medical Act, 1886, shall be deemed, from the date of this Order, to apply to the Kingdom of Belgium, until it is otherwise ordered ' Part II of the Medical Act of 1886 deals with the admission to the Medical Register of colonial and foreign practitioners holding medical diplomas recognised by the General Medical Council "as furnishing a sufficient guarantee of the possession of the requisite knowledge and skill for the efficient practice of medicine, surgery, and midwifery The new and welcome Order in Council authorises the General Medical Council to recognise for the time being medical diplomas of approved Belgian universities and thus to admit Belgian practitioners to the Foreign Section of the Register, with freedom to practise in the United Kingdom The Executive Committee of the General Medical Council will take the necessary steps to give early effect to this enactment

BAKING CHRONIC ULCERS OF THE LEG

IN the *New York Medical Journal* of Dec. 19th last Dr H D Sonnenschein has reported good results from the treatment of chronic ulcers of the leg by ' baking the part in an electric dry air oven at a temperature of 250 to 300 F for 20 to 30 minutes three times a week Sluggish granulations become healthy and active healing is astonishingly rapid and pain disappears after two or three treatments The following are examples A man, aged 63 years, had an ulcer of the size of the palm of the hand on the tibial surface of the left leg The urine contained sugar In diabetic and nephritic cases the patients can endure only low degrees of heat and are very susceptible to burns Therefore the oven is heated to a lower temperature than usual In this case 120 to 130 was adopted and the ulcer completely healed In another case a barman aged 42 years had an ulcer on the plantar surface of the foot following an injury received 14 years before It was 1½ inches square and three eighths of an inch deep and the edges were very hard There was no history of syphilis and the Wassermann reaction was negative The ulcer had not been treated for 12 years, and the patient sought advice in consequence of the pain, which was unbearable The ulcer was "baked" three times a week, cleansed with peroxide of hydrogen, and dressed with scarlet red ointment. Complete healing took place and the pain disappeared In a third case a man, aged 45 years, had an ulcer on the small toe of the left foot which extended for about an inch along the border of the foot Both feet were cyanotic and painful. In spite of the poor nutrition of the part the ulcer healed and the cyanosis and pain diminished under "baking" and the application of scarlet red ointment. Dr Sonnenschein considers that the method acts by induction of hyperæmia, which has been found very successful in the treatment of refractory chronic ulcers Among the means which have been adopted to induce hyperæmia are the application of Esmarch's bandage and the old but efficacious plan of immersing the part in a pail of very hot water We may point out that, as stated in an annotation in THE LANCET of June 14th, 1913 (p 1684), heat applied in another manner—a douche of hot air—has been used with success by French surgeons in the treatment of torpid ulcers In 1911 M Vignat recommended it, and at a meeting of the Societe Medicale des Hopitaux of Paris on May 16th 1911, M Mosny and M. Pruvost reported a case of sloughing bedsore in a patient in a bad condition after an attack of phlebitis and bronchopneumonia which rapidly healed under this treatment

THE CORPUS STRIATUM

SOME of the obscurity which has hitherto enshrouded our knowledge of the large mass of basal grey matter which is known as the corpus striatum appears at length to be dissolving away In spite of the fact that electrical stimulation of this region of the brain fails to elicit any definite motor response, yet evidence of lenticular degeneration can be clinically revealed by a syndrome of symptoms now fairly clearly recognisable in which motor disturbances, spasm and tremor, form prominent features Dr S A Kinnier Wilson, who has brought this 'lenticular syndrome" into prominence,[1] now records in *Brain* (1914, xxxvi., 427) the results of certain experimental lesions placed in this basal mass and discusses the significance of these observations Electrical stimulation of the lenticular nucleus failed to induce any motor effect, thus confirming the results of most other observers Electrolytic destruction, however, of definite portions of this nucleus was carried out on monkeys which after a period of three weeks, were destroyed and the degenerated areas carefully examined The results showed, in the first place that the corpus striatum is independent of the cerebral cortex, it is also not connected directly with the spinal cord Connexions are more intimate however with the optic thalamus and regio subthalamica, including the red nucleus and this fibre system links especially with the globus pallidus portion of the corpus striatum It is clear that this body is an behaviour in fatigue and under the influence of its nerves or chemical agencies, such as acid ions or adrenalin." A study of the heart shows that it is able to put out a constant amount of blood with very wide variations in the arterial pressure provided only that the venous inflow is constant. Indeed, if the inflow into the right ventricle is maintained constant, the output from the left ventricle is unaltered by the resistance presented by altered arterial blood pressure, by changed rate of beat. On the other hand, within wide limits the heart is able to increase its output in direct proportion to the inflow. A study of the respiratory exchanges of the heart shows that the metabolism of the heart increases or diminishes in proportion to the mechanical demands made upon it. The adaptation is complete, the chemical sources of energy are drawn upon in proportion to the heart's requirements. The heart, like any other living tissue, requires opportunity for recuperation. This it obtains normally by putting in its period of rest immediately after each period of activity. If a high degree of work for long periods is demanded of it it shows fatigue, which may go on to failure. As the three latest observers point out, this occurs when the dilatation, which is the mechanical result of unchanging inflow and failing outflow and is the automatic means of regulating outflow to inflow, proceeds to such an extent that the tension of the muscle fibres becomes increasingly inadequate in producing rise of intra-cardiac pressure. The mechanical disadvantage at which in the dilated heart the skein of muscle fibres must act finally smashes up the system and the circulation comes to an end.

[1] THE LANCET April 2[illegible], 1912, p 11[illegible]5

EPIDEMIC OUTBREAKS IN RUSSIAN FACTORIES

IN March and April of 1914 severe mysterious epidemics broke out in many Russian factories, most of which are in Petrograd. The evidence now forthcoming as to the origin of these epidemics is analysed in *Norsk Magazin for Laegevidenskaben* for October by Professor Harbitz, who, though he does not claim to have solved all the difficulties, argues that the main causes were chronic ill health and hysterical phenomena, which spread from patient to patient. The first outbreak occurred in a large Russian American rubber factory, which turns out millions of goloshes. The workers sit by hundreds at long tables in a large room, and their task consists of fitting the separate pieces together. The adhesive material used contains gutta percha and resins dissolved in benzine, the vapour of which constantly fills the room. It is a curious fact that though the factory has been in activity for 54 years symptoms of poisoning had not hitherto occurred, at any rate in the form of an epidemic. On the morning of March 25th one woman after another suddenly developed headache, giddiness, lassitude, collapse, and loss of consciousness. Nausea, vomiting, and convulsions were also observed. About 50 women were thus affected, a panic ensued, and a rush was made from the factory. Most of the patients rapidly recovered, but a few were confined to hospital for several days with headache and giddiness. On March 26th 102 similar cases occurred in another room of the same factory. The floor was strewn with writhing, unconscious women, and some men who rushed in to help also collapsed. An inspection of the room by medical men and the staff of the factory revealed nothing amiss. Next day the first room was opened again, but the women had scarcely begun work before a new outbreak occurred, 60 new cases being observed. All work was now stopped throughout the factory, but on March 28th, when the employees arrived to receive their weekly wages, several new cases occurred. On March 30th, when the factory was re opened, there were several new cases, but the symptoms were slighter. The employees now refused to work till several precautions had been taken. The whole factory was accordingly closed, and about 17,000 persons were out of work. The employees insisted that they had been poisoned by the adhesive material, the benzine of which had recently been changed. But this, according to the employers, was the purest benzine from Baku. They also remarked that the symptoms were practically confined to the women, although several men worked with them, and that, though the same solution was used in every room, the epidemics broke out now only in this room, now only in that. Medical men who investigated these outbreaks traced them to benzine poisoning, with which the symptoms tallied. They suggested that the cumulative effect of this drug had culminated in several persons at about the same time, and had affected women in particular on account of their weak constitution and physiological characteristics. Many neurologists, however, followed Professor Bechterew's lead in regarding these outbreaks as hysterical. Admitting that chronic poisoning might be at the bottom of these outbreaks, they maintained that their epidemic nature was due to auto suggestion and psychic infection. The upholders of the benzine hypothesis pointed to the occurrence of similar outbreaks in rubber factories in Riga. But their arguments were shaken when several similar outbreaks occurred in factories in which benzine was not used. Three tobacco factories were successively involved, and nicotine poisoning was consequently suspected till similar outbreaks occurred in factories devoted to such widely different commodities as chocolate, clothing, machinery, wool, and jute. To what extent these outbreaks were the expression of an agitation for better sanitary conditions it is impossible to say, but Professor Harbitz considers that they were mainly due to faulty sanitation and to chronic ill health, to which in some cases benzine may have contributed. The epidemic character of the outbreaks was, in his opinion, largely determined by psychic factors.

FLOODS AND POLLUTION

THE remarkable figures given by Lord Desborough at a meeting of the Thames Conservancy Board in regard to the extent of rainfall over the Thames basin for nine weeks ended on Jan. 5th last must mean an increased strain on the purifying machinery of the Metropolitan Water Board. In another column we publish a communication dealing generally with the increased demand upon the capacity of our sewerage system and its relation to public health. In the Thames basin the fall of rain was equal, we are told, to 3015 million tons, or 682,507 million gallons of water over the 3812 square miles of the area. It may be presumed that part, at any rate, of this flood water would be impounded in the storage reservoirs in order to keep up the domestic supply, and that in spite of the mass of impurities which it must sweep from agricultural land a good formed the subjects of coroners inquiries The first case was that of a young woman employed at an aeroplane factory at Rochester, who died from toxic jaundice with uræmic symptoms, the inquest was held on Jan. 5th The second case was that of a girl, aged 19 an employee at Vickers s works at Crayford, and at the inquest on Jan 8th the medical evidence showed that death occurred with symptoms of intense jaundice the result of toxic degeneration of the liver In each case the jury brought in a verdict of death from poisoning by tetrachlorethane vapour used in the aeroplane "dope" We understand that the Home Office are taking energetic measures to prevent the occurrence of any further accidents from this cause, but in view of the fact that tetrachlorethane and similar substances are being used in various parts of the country not only at aircraft works but in other industries—such as the manufacture of various preparations of cellulose—we think it advisable to draw public attention to the dangers involved in the employment of this very toxic chemical

A METHOD OF STAINING PARASITIC AMŒBÆ.

THE difficulty of satisfactorily staining the amœbæ of dysentery and allied forms is in practice considerable, so that any method which can be relied on to give good results is of interest The following directions are given in a recent communication by Mr Alexander Marshall,[1] of the Wellcome Tropical Research Laboratories at Khartoum Smears are made from dysenteric stools and transferred rapidly, while still wet to Schaudinn s fluid They are then washed in alcohol of different strengths and finally in distilled water, after which they are stained in Delafield s hæmatoxylin for 20 minutes They are next washed in tap water and stained with carbol fuchsin as for tubercle bacilli, after which they are again washed with water and finally differentiated with Sprengel s solution of picric acid, consisting of equal parts of absolute alcohol and of saturated watery solution of the acid This is applied for three to five minutes, during which time the reagent is changed three or four times The stained films are then dehydrated in absolute alcohol cleared in xylol and mounted in Canada balsam Thus treated, the nuclei of the parasites are stained a purplish black, while the cytoplasm is a pale translucent yellow colour Red blood corpuscles are also stained yellow The method is described as easy, rapid and certain in its results, and is certainly well worth trial by those called upon to make this investigation

NATIONAL ASSOCIATION FOR THE PREVENTION OF INFANT MORTALITY AND FOR THE WELFARE OF INFANCY —This association whose chairman is Sir Thomas Barlow has arranged for an advanced course of lectures on infant care for voluntary health workers mothers nurses &c. to be held at the Royal Society of Medicine 1 Wimpole street W on Mondays at 5 30 P.M from Feb 1st 1915 onward In addition to the lectures arrangements can be made for the attendance of every student at a four- [illegible] at selected infant welfare centres. For tickets and all further particulars application should be made to Miss Halford Secretary National Association for the Prevention of Infant Mortality 4 Tavistock square London W.C.

THE CLAIMS OF BRITISH SPAS

(*Concluded from Dec. 5th 1914, p* [illegible])

VIII.—WOODHALL SPA.

DEVELOPMENTS of real importance from a balneological point of view commenced at Woodhall Spa Lincolnshire, in 1887, since which time the place has advanced considerably The spa was brought prominently before the notice of the medical profession in 1909, when a large party of medical men from London and the provinces visited the place in response to an invitation of the directors of the Woodhall Spa Company to come and see for themselves the facilities for bath treatment offered at an increasingly popular health seeking station It is only three hours' journey from London, and is situated amongst most attractive surroundings of a rich moorland country with charming woodland scenes in which pine and birch trees chiefly figure The place has a restful air, and is well suited to the temperament of those persons who are likely to derive benefit from the therapeutic waters of the bromo iodine wells

The principal chemical feature of the Woodhall Spa water is the presence of both the bromide and iodide of potassium in distinctly important quantity, the former occurring to the extent of 3 51 grains per gallon and the latter to 0 53 grain per gallon The total saline matters present amount to 1562 48 grains per gallon, of which 1406 grains are due to common salt according to Professor T E Thorpe's analysis

Taken internally in small quantities this water is said to produce a sedative and tonic effect upon gastric and intestinal mucous membranes which is useful in some gastric and dyspeptic conditions In larger quantities the gastric activity is increased and chronic catarrhal conditions are benefited, while the functions of the pancreas and liver are stimulated and altogether a healthier state of nutrition ensues This alterative action of the waters is particularly observed in cases of rheumatism, gout, arthritis enlarged glands, and inflammatory exudations In full doses the water is mildly but distinctly purgative while effecting a marked diuretic action These waters, unlike so many natural waters which contain merely indifferent mineral constituents, show a composition upon which the explanation of their therapeutic action may reasonably be based The presence of bromide and iodide of potassium, for example, may be associated with definite therapeutic results, especially when they are accompanied by chloride of sodium In this matter the waters of Woodhall Spa are unique as no other mineral water in this country is known to contain such important quantities of the elements iodine and bromine

The external application of the water is provided for in many ways, a course of hot mineral baths being a routine of great assistance in cases of rheumatism and neuritis As an adjunct a hot spray is employed Local applications are given in the form of sprays and douches to joints, vapour inhalations and douches to the internal cavities of the nose and throat Compresses for application to painful joints have their basis in a specially concentrated mineral water which is further used in the form of douche or spray when a marked local reaction is desirable

The programme of social arrangements at Woodhall Spa is attractive but unobtrusive autonomous centre Its function is exercised independently of the cerebral cortex, but is motor in type, and is exercised in an *efferent or caudal* direction Developmentally, it appears that in the lower forms of vertebrate life the corpus striatum exercises a more dominant motor control than it can exert in the higher forms, although such control cannot attain the complexity and range afforded by the elaboration at a later phase of the cortical brain or neopallium The final function of the corpus striatum appears to be something of a "steadying" influence upon pyramidal innervation exerted through the strio rubro spinal tract How this effect is brought about is suggested to be by virtue of what Sherrington terms the 'final common path" The idea conveyed by this definition is that an end neuron effect, of motor type for instance, depends for its manner of action upon the particular stimulus applied to its arborisations at its proximal end, which stimulus, however, may be of varying nature, and may also reach the end neuron along different converging channels The type of final stimulus is itself determined by the coördinate relationships between the possible sources Amongst such channels are recognised cortical and cerebellar influences, for example, in addition, the corpus striatum is claimed to be capable of exerting an effect Clinically it is suggested that absence of striate control induces tremor, well exemplified in cases of progressive lenticular degeneration One question remains to be answered Why is it that in the experiments performed tremor did not result? The reason suggested is that possibly the wide variation in functional capacity of the lenticular nucleus in different species, a variation worthy, apparently, of particular comment, forbids the anticipation that results gained in experiments upon the ape need necessarily be identically reproduced in man

TRAUMATIC RUPTURE OF THE HEALTHY AORTA

IN the *Journal of the American Medical Association* of Nov 28th, 1914, Dr G G Copeland has reported a case in which death was due to a very unusual cause—traumatic rupture of a healthy aorta A labourer, aged about 40 years, was struck by a large mass of falling earth, which gave him a glancing blow on the back and knocked him down A few seconds later he was picked up dead Dr Copeland examined the body a few hours after death There was a large scalp wound on the fore head down to the bone, which was not fractured On the body were several small bruises, especially over the right loin, and the pelvis seemed to be fractured The face and mouth were blanched, suggesting internal hæmorrhage Nearly 10 ounces of blood were found in the peritoneal cavity The liver was badly torn and the right kidney was torn, but the capsule was intact The pelvis was fractured near the symphysis pubis, but the bladder was intact The peritoneal surface of the intestines and many of the blood vessels supplying them were torn With these lesions the abdominal cavity should have been full of blood The whole condition was explained when the thorax was opened The left pleural cavity contained 38 ounces of fluid blood Opening into this cavity were the gaping ends of the descending aorta, which was cut across as cleanly as if a knife had been used The ends were separated an inch at the widest part and half an inch at the narrowest The rupture was at right angles to the length of the vessel, which was quite healthy The intima was smooth and showed no plaques or dilatations The heart was firmly contracted and empty and was perfectly normal The distance from the aortic valves to the tear was 3½ inches The right lung was adherent to the chest wall throughout It was solid and non crepitant and its condition suggested the stage of red hepatisation of pneumonia The lower lobe of the left lung contained much coagulated blood Dr Copeland is unable to explain how the rupture was produced There were no external signs of the cause of death He suggests that the rupture of the aorta may have been due to a force of the nature of contrecoup

THE PROGNOSTIC VALUE OF SCHMIDT'S TEST IN SUMMER DIARRHŒA

DR J Sidney Pearson, of Perth, Western Australia, commenting on the value of the Schmidt test on the fæces in the *Medical Journal of Australia* (1914, vol i, p 491), considers it of considerable value from a prognostic point of view His data for such a conclusion are based upon 2000 cases, though from the text it is not clear whether all were tested or whether such tests were limited to the 400 cases to which he more particularly refers The test depends upon determining the presence or absence of altered or unaltered bile in the fæces, and is carried out in this way A teaspoonful of fæcal material is placed in a wide test tube, a little sterile water added, and well stirred with a glass rod The tube is then filled to four or six times the volume with a saturated solution of corrosive sublimate, the mixture well shaken, and allowed to stand for 12 hours By this time fæces if normal become coloured bright red If unchanged bile pigments are present the colour becomes green If no colour change occurs bile is absent, and the reaction is termed negative In summer diarrhœa it is found to be generally negative, with improvement a positive reaction occurs, a green or red colour appearing The point especially emphasised is that no single case ended fatally in which the Schmidt test continued positive or after treatment became positive Further, Dr Pearson never managed to cure a case in which the Schmidt test continued negative In a final series of 200 tabulated hospital cases the results were —

Discharged with Schmidt's test	Negative	77
	Positive	87
	Changing to positive	9
Died with Schmidt's test	Negative	27
		200

Some pathological data recorded by the writer show that changes in the gall bladder, absence of bile in the intestines, are found in these zymotic enteritis cases He also notes that the bright green stools are not due to unchanged bile, but to a chromogenic organism, frequently the bacillus pyocyaneus

POISONING BY TETRACHLORIDE OF ETHANE

IN our issue of Dec 26th, 1914, we reported at some length the proceedings at an inquest upon a man who died at Hendon from the poisonous effects of the vapour of tetrachlorethane contained in a 'dope' for varnishing aeroplanes Since then two further deaths from the same cause have ıer smaller towns Of the 66 uncertified causes of death, were registered in Birmingham, 13 in Liverpool, 5 each South Shields and Gateshead 3 each in Southend-on Sea d Sheffield, and 2 each in Stoke-on Trent, Bootle, Roch le, and Tynemouth

HEALTH OF SCOTCH TOWNS

ın the 16 largest Scotch towns with an aggregate popula n es imated at 2,344 400 persons at the middle of this year 5 births and 1100 deaths were registered during the week ded Saturday, Jan 9th The annual rate of mortality in ese towns, which had increased from 17 7 to 20 5 per 1000 the four preceding weeks, further rose to 24·5 per 1000 the week under notice During the 13 weeks of last arter the mean annual death rate in these towns averaged 8 against a corresponding rate of 14 9 per 1000 the large English towns The annual death rate last ek ranged from 12 5 in Motherwell, 14·0 in Ayr and 7 in Perth, to 26 3 in Glasgow, 28 2 in Aberdeen, and 30 0 Dundee

The 1100 deaths from all causes were 201 in excess of the mber in the previous week and included 117 which were erred to the principal epidemic diseases against 77 and 93 the two preceding weeks Of these 117 deaths, 55 resulted m whooping-cough 21 from diphtheria 17 from infantile rrhœal diseases, 13 from scarlet fever, 7 from measles, and rom enteric fever but not one from small pox. The mean nual death rate from these diseases was equal to 2 6, ainst 1 4 per 1000 in the large English towns. The deaths ributed to whooping-cough which had been 35 28 d 44 in the three preceding weeks, further rose to 55 last ek, of which 38 occurred in Glasgow, 8 in Dundee, 4 in eenock, and 2 in Clydebank The deaths referred to diph eria which had been 9 16 and 14 in the three eceding weeks rose to 21, and included 7 each in asgow and Edinburgh and 5 in Aberdeen The fatal ses of diarrhœa and enteritis (among infants under 2 years) ich had been 15, 12 and 11 in the three preceding weeks, se to 17 last week, 5 deaths each were recorded in asgow and Dundee and 3 in Edinburgh The deaths ributed to scarlet fever which had been 17 15 and 17 in e three preceding weeks fell to 13 last week, and included n Glasgow The 7 deaths referred to measles were 4 in cess of the weekly average during last quarter, and com ised 6 in Dundee and 1 in Aberdeen Of the 4 fatal cases of teric fever 2 belonged to Glasgow and 1 each to Edinburgh d Paisley

The deaths referred to diseases of the respiratory system, ich had increased from 154 to 210 in the four preceding eks, further rose to 235 in the week under notice, 32 aths resulted from different forms of violence, against 35 d 42 in the two preceding weeks

HEALTH OF IRISH TOWNS

In the 27 town districts of Ireland with an aggregate pula ion estimated at 1,212,350 persons at the middle of is year 649 births and 615 deaths were registered during e week ended Saturday Jan 9th The annual rate of ortality in these towns which had been 21 8 17·0 and 8 per 1000 in the three preceding weeks fell to 26·5 per 00 in the week under notice During the 13 weeks of st quarter the mean annual death rate in these towns eraged 18 8 against corresponding rates of 14 9 and 16 8 r 1000 in the English and Scotch towns respectively The nual death rate last week was equal to 36·5 in Dublin ainst 20 1 in London and 26 3 in Glasgow, 21·0 in Belfast 1 in Cork 13 9 in Londonderry 33 8 in Limerick and 8 in Waterford while in the 21 smaller towns the mean ath rate was 20 5 per 1000

The 615 deaths from all causes were 23 fewer than the mber in the previous week and included 33 which were erred to the principal epidemic diseases against 32 and 42 the two preceding weeks Of these 33 deaths 11 resulted m whooping cough 11 from infantile diarrhœal diseases rom measles 5 from diphtheria, 3 from

The deaths referred to diseases of the respiratory system, which had been 105, 96 and 162 in the three preceding weeks, fell to 139 in the week under notice Of the 615 deaths from all causes, 182, or 30 per cent, occurred in public institutions, and 6 resulted from different forms of violence The causes of 30, or 4·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest in the English towns the proportion of uncertified causes did not exceed 1 0 per cent

THE SERVICES

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned has been entered as Surgeon for temporary service in His Majesty's Fleet —Robert Sharp Lawson

The undermentioned have been granted commissions as Surgeons for temporary service in His Majesty's Fleet, and have been appointed to the *Pembroke*, additional, for Chatham Hospital —James Edward McCausland and Frank Reginald Featherstone

ROYAL ARMY MEDICAL CORPS.

Fred D Bird to be temporary Lieutenant-Colonel (dated Dec 3rd, 1914)

To be temporary Captains —Dated Dec. 16th, 1914 Robert Sewers Berry Dated Dec 21st, 1914 Edwin Arthur Peters and Arthur Robert Owst. Dated Dec 23rd, 1914 John Davies

Temporary Captain Frederick F Bond resigns his commission (dated Jan 9th)

To be temporary Lieutenants —Dated Dec 5th, 1914 Alfred Cecil Edwards Dated Dec 7th, 1914 Bertram Mayhew Bone, William James Gifford Gayton, and Hans Fleming Dated Dec 8th, 1914 James Alexander Hendry John Daniel Harmer, Carl Joseph Barrett Buchheim Frank Anthony Cooke, Arthur John Ormsby Wigmore, and James Aubrey Ireland Dated Dec. 10th, 1914 Victor Vesselovsky and Wilfrid Henry Waller Attlee Dated Dec 11th, 1914 David Hutcheon Paul Dated Dec 14th, 1914 Martin Hallam and Stephen Nockolds Dated Dec 15th 1914 George Barrowclough Horrocks and Herbert Park Shackleton Dated Dec 16th, 1914 David Henry Griffiths, David William Jones, Gwilym Llewelyn Pierce William Frederick Gibson John Allan, John Henry Herbert Pearson, and George Edward Genge-Andrews Dated Dec 18th 1914 George Ramsey Phillips Frank Hendry Rae Philip Hugh Rawson George Richardson, and William George Thompson Dated Dec 19th 1914 Harold Cane Godding and William Richard Spencer Watkins Dated Dec. 20th 1914 Alexander Emil Albert Burkhard. Dated Dec 21st 1914 William Miller Thomas John Burton Robert Percy McDonnell Harry Godfrey Massy Miles, Arthur George Grant Plumley Kenneth Dobing Bean, Philip John Ambrose Seccombe, William Stewart Dickie, Joseph Graham Edward William Lawrence, Harry Spencer Hall, George Pirie Geoffrey Bower Richardson, Kenneth Goodall Hearne Percival Butler and Alexander Campbell White Knox Dated Dec 22nd 1914 Donald Olson Riddel and Arthur William Stark Christie

Lieutenant Edward M Woodman relinquishes his temporary commission

Temporary Lieutenant Alfred G Stewart and Temporary Lieutenant Philip L Davies relinquish their commissions (dated Jan 10th)

SUPPLEMENTARY TO REGULAR UNITS OR CORPS

Royal Army Medical Corps

Lieutenant Robert McCheyne Linnell to be Captain

The undermentioned Lieutenants are confirmed in their rank —Douglas G Evans Charles C Iles Frank Griffith John P Mitchell Donald G J McEntire, Edward C Linton Ennis R Chambers John L Per

IX.—PEEBLES

Peebles, described as "the leading Scottish health resort," has qualities of environment which, coupled with the facilities for a hydropathic course, deserve to be more widely known. It is beautifully situated on the River Tweed, amidst a delightful panorama of hill, valley, and wood It is a peaceful, restful place where "rest cures" do genuinely occur All the accessories which form part and parcel of modern treatment by baths are to be found here on lines comparable with the installations of a spa abroad A particular feature is made of the mud pack or "fango" for the relief of such painful affections as gout, rheumatism, and sciatica The Nauheim and Bourbon Lancy methods of treatment of heart affections are available The historic St Ronan's wells not far from the "hydro" entitle Peebles to the description of a watering place, the waters being brought to the hotel for special bathing purposes They are saline and sulphated

X., XI , XII —THREE WELSH SPAS

There is a wealth of natural mineral waters in Wales, and three spas have commanded medical support

Llandrindod is among the best known inland watering places, and the town has developed rapidly in recent years as a well recognised balneological station Here are common salt and sulphur springs, the latter resembling the waters of Harrogate in containing sulphuretted hydrogen gas The saline waters are employed chiefly in catarrhal dyspepsia and hepatic disorders, while the sulphur waters serve as an adjunct in the treatment of gouty and rheumatic states

At Llangammarch, about 13 miles south of Llandrindod, is a spring containing common salt, calcium chloride, and barium chloride Therapeutically the water is said to be similar in action to that of Kreuznach, and chemically it is, we believe, the only example of a natural mineral water containing so much barium salt It is used in the treatment of chronic heart disorders, functional distress, in Graves's disease, and in rheumatic conditions The action of barium chloride has been compared with that of digitalis The water is employed both internally and externally Its composition seems well adapted for preparing a Nauheim bath The country round is very beautiful, the Eppynt Mountains sheltering the village from the north east Treatment is provided for at the principal hotels, which have recently been greatly developed on lines consistent with the requirements of a large clientèle of patients and visitors

Llanwrtyd some five miles south of Llangammarch, is known chiefly on account of its strong sulphur wells, and the cases treated here are commonly skin disorders, rheumatism and gout There is excellent accommodation, and the bathing installations provide for most lines of treatment

THE BRINE BATHS AT STAFFORD

Dr F Milnes Blumer medical officer of health of Stafford, has pointed out to us that at Stafford there is a brine of a potency equal to that at Droitwich which is utilised in the complete suite of baths opened by the corporation in 1892 Chemical analysis of the brine shows a similar composition in regard to saline strength Of course there are brine wells in other parts of the country, and all are more or less saturated solutions of common salt. In th series of articles we were dealing more partic larly with those places generally recognised health resorts or spas We are glad to note, ho ever, in bringing this series of articles to a clo that at Stafford the brine wells are used f remedial purposes

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN November last the county borough of Plymouth w extended to include Devonport, thus reducing the numb of towns with populations exceeding 50 000 persons at t last Census to 96 In these 96 towns 9434 births and 6 deaths were registered during the week ended Saturd Jan 9th The annual rate of mortality in these tow which had been 16 1, 14 0, and 21 3 per 1000 in the thr preceding weeks, fell in the week under notice to 1 per 1000 of their aggregate population, estimated 18 134,239 persons in the middle of 1914 During the weeks of last quarter the mean annual death rate in the towns averaged 14 9 against a corresponding rate of 15 3 p 1000 in London The annual death rate last week ran from 7 3 in Acton 10·0 in Croydon, 11 6 in Barnsley, 11 Newport (Mon), and 12·0 in Ilford to 26 9 in Northamp 27 1 in Hastings, 28 0 in York, 28 2 in Preston, and 47 9 Gillingham

The 6736 deaths from all causes were 659 fewer than t number in the previous week, and included 487 which we referred to the principal epidemic diseases, against 4 and 575 in the two preceding weeks Of these 487 deat 183 resulted from measles, 93 from whooping-cough from infantile diarrhœal diseases, 77 from diphtheria from scarlet fever, and 15 from enteric fever, but n one from small pox The mean annual death rate fro these diseases was equal to 1 4, against 1 7 per 10 in the previous week. The deaths attributed to measle which had been 210, 175, and 269 in the three p ceding weeks, fell to 183 last week, and caused t highest annual death rates of 1 7 in Bolton and Gateshead, 2 1 in St Helens 2 3 in Wigan and Newcastle-on Tyne, 2 5 in Merthyr Tydfil, 2 7 in Grimsb 4 4 in Plymouth, and 4 8 in Preston The deaths referre to whooping-cough, which had steadily increased from 35 to 80 in the seven preceding weeks, further rose to 93 las week , the highest death rates from this cause were 1 1 Newcastle-on Tyne, 1 3 in Rhondda, 1 4 in Bristol an in Warrington, 1 6 in Willesden, 1 7 in Tynemouth, an 1 9 in Gillingham The fatal cases of diarrhœa and enter (among infants under 2 years), which had been 81, 70 and 86 in the three preceding weeks, slightly fell to 84 last week and included 18 in London, 7 in Birmingham and 5 each in Manchester, Oldham and Sunderland The deaths attributed to diphtheria, which had been 70 66, and 83 in the three preceding weeks, fell to 77 last week, of which 19 were registered in London, 5 in Liverpool 4 in Birmingham, and 3 each in Southampton, Birkenhead Preston, and Sheffield The deaths referred to scarlet fever which had been 34, 30 and 31 in the three preceding weeks rose to 35 last week 6 deaths belonged to London, 4 to Sheffield, 3 to Newcastle-on Tyne, and 2 each to Birmingham and Preston The fatal cases of enteric fever which had been 14 12 and 20 in the three preceding weeks, fell to 15 last week of which 5 occurred in London and 2 in Bolton

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had declined from [illegible] to 4503 in the six preceding weeks had further fallen to 4152 on Saturday last, 320 new cases were admitted during the week, against 451 348, and 435 in the three preceding weeks. These hospitals also contained on Saturday last 1649 cases of diphtheria 65 of measles 60 of enteric fever and 36 of whooping-cough but not one of small pox. The 1738 deaths from all causes in London were 311 fewer than the number in the previous week and corresponded to an annual death rate of 20 1 per 1000. The deaths referred to diseases of the respiratory system which had been 313 270 and 562 in the three preceding weeks fell to 497 in the week under notice, and were 14 below the number recorded in the corresponding week of last year

Of the 6736 deaths from all causes in the 96 towns [illegible] resulted from different forms of violence and 565 were the subject of coroners' inquests while 1757 occurred in publi institutions The causes of 66 or 1·0 per cent. of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest All the causes of death were duly certified in Manchester Leeds Bristo West Ham Bradford Hull, Newcastle-on Tyne and in 6 the probe can be manipulated quite easily, the lights turned out, and the movements of the probe watched on the fluorescent screen by the radiographer, who by simply moving his X ray tube to and fro, in the manner described by Mr Shenton in his article, can accurately direct the movements of the probe up, down, or to either side, and can lead the point to the bullet almost at once, when the surgeon will have audible confirmation of the discovery in his telephone receiver It is remarkable how quickly this can be done, a few seconds sufficing for a task that usually occupies many minutes The probe once touching the bullet, it is an easy matter to remove the telephone attachment, cover the probe and incision with a small temporary dressing, which also serves to keep the probe from slipping out, and remove the patient to the theatre, where the surgeon, with such a guide can easily cut down on the bullet, either by enlarging the small incision or in another direction altogether, this latter method obviating any danger of moving the probe while operating The difficulty is to keep the probe from shifting during the moving of the patient to the theatre, and during the ensuing operation, in which case one s trouble is wasted To guard against this we are going a step further and completing the entire operation on the X ray table, when screen examinations can be made at intervals if the case presents any extraordinary difficulties In ordinary cases these are generally unnecessary

My X ray room here with certain small preparations, such as special lighting, is perfectly suitable for operating, and the table, with a polished wood top, lends itself quite well for the purpose Of course, the unpractical and complicated design of many X ray tables makes their use in this way impossible, but any of the wooden topped tables with an efficient tube moving device below can be utilised with some degree of success I am constructing a special table for this purpose, closed in at sides and ends, and giving clear access all round for the surgeon, dressers, and the anæsthetist, also having all movements of tube box, switch, diaphragm and regulating device all controlled by one foot With some such table as this, and a means of darkening the room effectually and rapidly, I can see no reason why all bullet extraction operations, and possibly certain bone operations, should not be carried out with the aid of X rays, facilitating and shortening enormously what is usually a tedious and difficult performance

I am, Sir, yours faithfully,

C F CONSTANT,
Lieutenant R.A M C Radiographer to the Meerut
Indian General Hospital.
Brockenhurst Hampshire Jan. 5th 1915

THE PROPHYLACTIC TREATMENT OF PUERPERAL INFECTION BY DILUTE SULPHURIC ACID

To the Editor of THE LANCET

SIR,—I am entirely indebted for the idea of this mode of treatment to the valuable paper in THE LANCET of March 15th, 1913 by Dr J Reynolds and Dr Russell J Reynolds entitled, "On the Treatment of Carbuncles Boils, Staphylococcic Infections and Certain Streptococcic Infections by the Internal Administration of Large Doses of Dilute Sulphuric Acid B P

I think the medical profession owe a debt of gratitude to Drs Reynolds for the discovery of this valuable therapeutic measure The prophylactic treatment of puerperal infection I advocate is simply an extension of their mode of treatment to another septic condition, or I should say to the *prevention* of a septic condition, for just as I am firmly convinced that the administration of large doses of dilute sulphuric acid has a powerful effect on limiting and aborting such conditions as boils, carbuncles, so I believe the administration of this remedy has a powerful effect in increasing the resisting powers of the tissues to infection, and thus preventing infection if given early enough in such cases as childbirth, where there is a large wound surface, and always a possibility of infection.

After seeing the paper referred to above by Drs Reynolds I commenced using the remedy as described by them for boils, carbuncles, and similar conditions The improvement in most cases was both rapid and remarkable I then decided to use the drug in puerperal cases in which there was any degree of puerperal morbidity, in the hope that it would limit the septic condition, as in the cases of boils, carbuncles, and other infections The clinical results in the few cases tried were satisfactory, the administration of the drug being followed by a reduction of the pulse rate and lowering of the temperature

I then decided to use the drug as a prophylactic measure against infection in all labours in which there had been manipulations or operative interference, commencing the administration immediately after labour and continuing during the puerperium I now use it as a routine treatment in all labours, whether instrumental or not I think the action of the drug is due to the fact that when given in maximum doses it decreases the alkalinity of the blood

I quite agree with Drs Reynolds that the drug is useless unless given in maximum doses I give it in 20 minim doses, with 30 minims of tinc aurantii and water to one ounce, an ounce every four hours in an ounce of water It is difficult to judge by results in the prophylactic treatment of any disease, as there are so many other factors to be taken into consideration, but I believe the drug is worthy of a real trial in the treatment of puerperal infection, and more especially as a prophylactic measure against infection I believe the diminution in the alkalinity of the blood increases the resisting forces of the tissues to infection, but this needs further proof

The one case of puerperal infection I have seen in which the dilute sulphuric acid had no beneficial effect was a case I saw in consultation—acute septicæmia I suggested trying large doses of dilute sulphuric acid it had no effect The patient ultimately died I was told shortly afterwards by a lady friend of the patient that for three or four weeks previous to her confinement the patient had been in the habit of taking three times a day a teaspoonful (heaped up) of sodium bicarbonate moistened with a little water to relieve indigestion and flatulence Might not the large doses of sodium bicarbonate have increased the alkalinity of the blood, and so reduced the resisting powers of the tissues to infection, and might it not have counteracted any beneficial effect the acid might have excited ? These are questions of the utmost importance

I make no apology for bringing forward the subject of the prophylaxis of puerperal infection, it is one of vital importance The mortality from

North Somerset Private John Henry Trentham Polehampton, from the 2nd South Western Mounted Brigade, Field Ambulance, Royal Army Medical Corps, to be Second Lieutenant

Royal Army Medical Corps

Welsh Border Mounted Brigade Field Ambulance Lieutenant Devonshire P H Gardiner, from Attached to Units other than Medical Units, to be Captain (temporary) Walter Stuart Snell to be Lieutenant

1st East Lancashire Field Ambulance Leonard Emilius Harman Ross Barker to be Lieutenant

"Audi alteram partem"

THE LOCALISATION AND EXTRACTION OF BULLETS

To the Editor of THE LANCET

SIR,—Mr E W H Shenton's exposition of his extremely practical and common sense method of localising bullets, published in THE LANCET of Jan 2nd, cannot fail to be of great utility in the only too numerous cases of gunshot wounds with which surgeons and radiographers are inundated in these troublous times I have employed Mr Shenton's methods of localisation for some years, mainly in South America, a country where one has more opportunities for the study of gunshot wounds than in Europe—that is to say, in times of peace—and I have always been able to obtain an accurate estimate of the position of the bullet in a very short time But the matter by no means ends with the localisation However accurate the radiographer's report and skin markings may be (I agree with Mr Shenton that photographs are useless in the vast majority of cases), it is often by no means an easy task for the surgeon to remove the bullet or piece of shell easily and expeditiously Exigencies of local injury or anatomical difficulties may prevent the surgeon from making more than a small incision, very possibly in an awkward plane, and furthermore the topography of the part, clear enough in an X ray or clinical examination, may become considerably obscured when the case is on the operating table, covered over with towels and dressings, so that, even with the most accurate X ray localisation, the surgeon has to hunt about considerably before discovering the object sought for This may not be the experience of all surgeons in this class of work, but we have certainly found it so in this hospital in the considerable number of operations for removal of bullets that we have already performed

In consequence, on the suggestion of Captain A H Proctor, I M S, the surgeon to this hospital, we have evolved the following method of coöperation between surgeon and radiographer, which we find simplifies the operation to a great degree, and, what is more important, shortens enormously the time occupied The patient is anæsthetised upon the X ray table, or, if preferred, local anæsthesia can be used A very small skin incision, just large enough to admit the point of a probe, is made near the bullet, already localised by the X rays, at a point selected with due regard to anatomical requirements and the convenience of the radiographer, who will need the probe to be inserted in a direction somewhere near the horizontal A long stout silver probe, fairly sharp at the point, and provided with the well known "telephone" attachment, is inserted in the incision and gently forced through the tissues in the direction of the bullet (It is almost superfluous to say that the probe point should be just sharp enough to worry through the softer tissues, without doing any damage to vessels or nerves Here we are using a stout 9 inch probe, filed to an edge at the eye end) With the probe so introduced the surrounding parts and the surgeon's hands are covered with a sterilised towel, under which

The condition is lower, more degrading, than that of prostitution No doubt a large number of lecturers, coaches, and professors will undergo a financial loss by a falling off in the number of medical students, so will the medical examiners of students for their diplomas No doubt some of the young men who have gone to the war and who would have otherwise entered as medical students will so enter when the war is over The present drop is partly due to the war No doubt it is also a reaction against the sadly over crowded condition of the medical profession We can accept Sir Donald MacAlister s statement that if the falling off in the number of medical students continues there may be a falling off in the number of doctors of 200 to 300 yearly

So great was the dangerously overcrowded state of the medical profession that in 1886 the Medical Council issued a very ominous report, giving a census of medical practitioners in England and Wales That report showed that in 1881 there were 15,022 practitioners registered in England, and in 1886 16,930, showing *a rate of increase* of 2 42 per cent per annum In the former year there was on an average 1 *practitioner* to 1747 persons, while in 1886 the average was 1 to 1662 Therefore the doctors had increased at the rate of 2 42 per cent per annum, while the general population had increased by only 1 40 per cent per annum Why, therefore, should we bemoan the fact that the number is still falling? If there be healthy law in that of supply and demand, why should we when having a falling death rate, a falling sick rate, and a falling birth rate contend that we must have a *rising* increase of doctors? It is generally accepted that we should have on an average about 3500 persons to each practitioner, for it must be recollected that fully one third of the population receive free medical treatment and another third for a little above nothing It is a pity Sir Donald MacAlister did not refer not only to the number of students but also to the number of doctors practising in the United *Kingdom* According to the Medical Directory (not the Medical Register) the following *table* shows the number of doctors practising in each division of the United Kingdom on Jan 1st, 1915 —

		Population
London	6 715	36,070,492
Provincial	18,109	
Wales	1 415	
Scotland	4 070	4,760 904
Ireland	2 971	4,390,219
Total	32 290	

It will thus be seen that there is 1 doctor to 1401 persons of all ages, all incomes, and classes It is also instructive to note that the increase of the number of practitioners for 1914 was 527, for 1614 158 and 1813 260 Therefore the number of practitioners is *going up by* hundreds, while the proportion of doctors to the population has increased by 1 practitioner to 1041 persons In 1886 it was 1 to 1662

If it be contended that there are not *at present* sufficient doctors for war and other purposes I would suggest that such a condition—if it exist—could readily be met At present a number of practitioners are employed to examine children at the elementary schools 317 acting as principal medical officers and 524 as assistant medical officers Supposing the c 841 are required for war purposes it would be quite easy to fill their places by the doctors who practise in the school locality Or again a large number of those who act as resident medical officers to Poor law, voluntary, and municipal free hospitals could be taken for war purposes if their places were temporarily filled by the local practitioners who do not hold hospital posts The *time must come when a full staff of* visiting physicians and surgeons must be appointed to all the large Poor law hospitals, and this is the time to make a beginning I should not think that 5 per cent of the practitioners in the United Kingdom have been called away to join the army and navy, for according to the Medical Directory there were 3366 medical *officers* in *our* navy and army last year Poor law guardians and others must not think there is a "shortage" of doctors simply because they cannot obtain a resident medical officer or a visiting medical officer for £50 to £120 a year The school medical officer, whose duties are very light, obtains a minimum of £250 to £300 per annum from the majority of the educational authorities

I am, Sir, yours faithfully,

Liverpool Jan 11th 1915. ROBERT R RENTOUL

OUR ARMY'S TEETH

To the Editor of THE LANCET

SIR,—The dental expert going to the war with the intention of doing good for poor Tommy's *teeth* is at first confident that it is simply a matter of money, and he *thinks that* if he had a blank cheque from Mr Lloyd George he could put things right, but after three months' toil and vast worry he begins to understand that even with the Bank of England at his back he could not evolve a sound scheme under existing conditions And things are growing worse, for the teeth of those who are coming out now are not even so good as *those of* the earlier arrivals It seems probable that when the New Army has arrived there will be battalions of men to return on account of their teeth. It is no rare sight *to find a* young soldier who has not two back teeth that meet, and dozens of men have to be reported as dentally unfit for service It would be wearisome to state the causes and complications at length, but I inscribed many of their reports with brief remarks which, if strung together in readable form, represent the pith of my experience "Dental caries is avoidable, it is due to dental dirt and nine tenths of it would be obviated if the teeth were brushed *properly* after every meal The British army abandoned its tooth brush during the *Great* Retreat, and it has not been seen since If the Jap' can clean his teeth on the battlefield, so can the English Extra pay should be given for good teeth, and there should be *an* army dental corps to keep them right Allowances to soldiers, their wives and children, in time of peace should cease whilst their teeth are neglected Children should be taught to clean *their teeth after* every meal from the time they cut the first milk tooth '

Statistics are less hateful when quoted in millions, and we are expecting *one or* two million soldiers within the next few months Apart from the edentulous, each *man will require* on the average a filling or two, probably several fillings To *put* it very mildly, there will be several million fillings required and the crucial question is, 'Can it be done here?' I believe it is too big a thing without a mobilisation order Gladly would I see my profession get its order to march Many of the young men would be stationed behind the trenches in order to destroy an exposed pulp or to do a filling or two for a man who was otherwise sound Others puerperal infection is still far too high in spite of all our antiseptic precautions.

We have so far devoted all our attention to the perfection of our antisepsis, but surely the question of increasing the resisting powers of the individual to infection is one of real and practical importance. My own experience is too limited to give a definite opinion as to the exact value of this drug as a prophylactic agent, but from my own observations it certainly is of value in mild cases of puerperal morbidity. All that I ask is that an extended trial may be given the treatment by those who have greater opportunities of studying its effects, and if it is found, as I believe it will be, that the treatment is of real value, the medical profession will owe an increased debt of gratitude to the introducers.—I am, Sir, yours faithfully,

Congleton. J. L. MOIR, M.B., Ch.B. Vict.

A SUGGESTION FOR A NEW "BOWEL PACK."

To the Editor of THE LANCET.

SIR,—In introducing this simple contrivance to the notice of the profession I do so more to meet the difficulties experienced by general surgeons like myself than to offer assistance to those who never find any difficulties in any circumstances. The ordinary "bowel pack" is, I think, open to objections. Indeed, to start with, the packing of protruding bowel with many feet of gauze pads, &c., is to my mind unscientific, takes time, unnecessarily blocks a limited space and in the end does not always attain its object. Something is required completely to shut off the bowels from the area to be operated upon, which does not take up unnecessary space, which can be easily moulded, and will retain its position.

To meet these requirements I coil fine wire between two layers of lint. The fine wire gives a certain amount of weight, and it can be moulded and bent into any shape. These pads can be made by any nurse. A piece of lint the size of the pad required is simply laid flat, then starting from the centre the fuse wire is coiled in oblong fashion, tacked at each corner at first, and down the long sides as the oblong enlarges until the lint is covered, a second piece of lint is then placed over the wire and sewn round. I use pads varying in size from 15 or 18 inches by 10 to 9 by 5. For large size pads I use what is known as 5 amp fuse wire and for smaller ones 3 amp wire. The wire should be one third of an inch apart in the large and one quarter in the small. It is convenient to use the wire coiled upon its original reel. Only one precaution is suggested—namely, to begin and end the wire with a small loop so as to leave no free point. The pad can be thoroughly sterilised by boiling and squeezed out in warm saline before use.

To illustrate the advantage of this pad I will briefly quote a recent case when the contrivance proved very valuable. A lady was sent to me with a large fat abdomen, presenting a central scar. To the left of the scar was a large rounded swelling, diagnosed on several occasions as a ventral hernia. Vaginal examination disclosed a displaced uterus and little more. I made a large oval skin incision and removed the scar, together with a two inch thickness of fat. A good view could then be obtained. The left rectus was thinned and bulged up by some underlying tumour. I next opened the old scar and peritoneum, and at once introduced one of my largest pads with its long axis transversely.

In introducing the pad I had pressed it together, then opened out, and packed well down to the post abdominal wall, then pushed the upper edge well under the anterior wall above the umbilicus. Next I pressed the whole of the pad upwards. The tumour, a right ovarian cyst measuring about 8 inches by 8, presented itself quite free from any bowel. I then freed the cyst, carefully tied it off with tape, clamped and sutured in the usual way. The pad was then removed quite easily without any disturbance of the bowels.

I have found this pad very useful in packing bowel away from large appendix and pyosalpinx abscesses and in various other abdominal operations. The necessity to use only one pad does away with many anxieties and achieves a definite object.—I am, Sir, yours faithfully,

J. L. AYMARD, M.R.C.S., L.R.C.P.

Johannesburg, Dec. 15th, 1914.

THE "SHORTAGE" OF DOCTORS.

To the Editor of THE LANCET.

SIR,—The President of the General Medical Council has stated that the number of medical students now studying is about 1000 less than in 1913. He adds that the prospective diminution of our reserve supply of doctors calls for serious attention.

Sir Donald MacAlister gives no reasons for this falling off. There is little doubt but that the falling off in the number of medical students is due to the medical arrangements under the National Insurance Acts. Before these Acts were passed the newly qualified doctor could look forward to making sixpenny, shilling, and half crown fees from a portion of the public now supplied under the Insurance Acts.

He also finds that these Acts have robbed him of the money he used to make by the supply of medicines, a loss of about £1,360,000 yearly. He finds that his private vaccination is now largely carried out by public vaccinators, that about three fourths of his obstetric practice has been transferred to midwives, that the school board medical officers now examine, and in some places treat, the sick children, that many more patients are going into the Poor-law, voluntary and municipal fever hospitals and into sanatoriums for consumptives, that the birth rate and sick rate are falling, and that prescribing chemists and quacks of all kinds are on the increase.

How can anyone hold that to encourage an increase in the number of medical students would not be a national danger? Doctors are called upon to perform many criminal acts, but if my "poverty but not my will consents" be a valid excuse, then an overplus of doctors is indeed a danger. The existence of so many medical and surgical homes will soon—if it have not already—become a public danger. Some can recall the grave dangers due, years ago, to doctors owning and "running" private asylums. Instead, therefore, of deploring a falling off in the number of medical students we should all rejoice at the fact. It will be a true gain to the public. For if there be anything more damnable in this world than a doctor having to go on his knees to pray to heaven to make his neighbours ill, so that he may provide daily bread for himself, his wife, and children, I should like to know of it.

The Belgian Doctors' and Pharmacists' Relief Fund

THIS FUND is being raised to organise relief for Belgian Doctors and Pharmacists, both those remaining in Belgium and those who are refugees in this country

Sir WILLIAM OSLER, Bart

Mr H P SYMONDS

Dr W COLLIER

would be attached to all the hospitals on the way to the base At every large hospital or base there would be an efficient dental department sufficient to attend sick and convalescent men and to repair artificial teeth Only the overflow and bad surgical cases would go to the ultimate base in London The question arises as to how far this system can be adapted to existing conditions The small number of dental officers with the army will be lost amongst one or two million soldiers So nearly everything must go to London for treatment There, of course, they will be distributed amongst all the hospitals, dental departments, and clinics which appoint dental surgeons in town and in the country Many of the men are ready to pay for artificial teeth at about hospital prices, and when a man has bought his own teeth he is inclined to take great care of them

One naturally inquires how the French soldier gets on with his food, and I am told that the French piou piou is no better off than our Tommy in the matter of teeth, but his food is softer and generally consists of soup, meat, and vegetables all cooked together Our men get "stew," but what they really like is a good bit of beef when they can eat it

Under the recommendations that I have made we should get rid of most of the dental caries without treatment beyond inspection, but the fight to insist on dental cleanliness would be long and bitter Unfortunately we cannot say that even the most educated and enlightened people are cleanly in the matter of their teeth Their mouths would not stand inspection, and their tooth brush would not always be beyond criticism in these days of oral sepsis —I am, Sir, yours faithfully,

• DEGLUTITION IN ACUTE TONSILLITIS

To the Editor of THE LANCET

SIR,—A recent personal painful experience has brought to my knowledge a fact of which I was previously unaware, and which I hope may prove of comfort and service to those who suffer from acute tonsillitis and those who have the care of them An attack of acute tonsillitis chiefly affecting the right side had rendered deglutition whether of liquids or solids a matter almost of impossibility on account of the pain it caused Under such circumstances one naturally inclines to keep all food in the opposite side of the mouth, and so as far as possible from the affected part, and those who have suffered will remember well the pain that occurs when the bolus is delivered into the grip of the pharynx.

Quite accidentally I discovered that the pain on deglutition is very much less if the food be prepared, so to speak, and collected on the affected side, then when the act of deglutition occurs it would seem that it is projected against the opposite side of the pharynx and so misses the acutely tender part What the exact mechanism of this manœuvre is I do not know, but I am able to bear witness of the very great difference it makes to one's comfort when it is adopted Fortunately the inflammatory condition in my own case did not exist long enough to enable me to carry out any number of experiments, but as far as they went they confirmed the initial one This small fact may be known to many, but to those who are unaware of it it may, I hope, prove of service

I am, Sir, yours faithfully,

THOS H KELLOCK.

Upper Wimpole-street, W Jan 6th 1915

THE ETIOLOGY OF POLIOMYELITIS

To the Editor of THE LANCET

SIR,—An interesting fact in Dr George Jubb's paper published in THE LANCET of Jan 9th is the occurrence of cases of poliomyelitis at West Kirby for the third year in succession in the same parish This, I think, is an unusual experience in this country My own experience with poliomyelitis has indicated as frequent coincidences the proximity to an infected cottage of stables or cowsheds, the presence in the house of several specimens of stomoxys calcitrans (the biting stable fly), and not infrequently direct evidence of the child having complained of the flies biting Anderson and Frost have supplied direct experimental evidence of the conveyance of polio myelitis infection by stomoxys from artificially infected monkeys to other monkeys

It would therefore be of much interest to know the relative position of the infected houses in West Kirby and Hoylake to the nearest stables or cow sheds (distances should be given approximately in yards) This information would be of value, but the case for the stomoxys would not be limited to such evidence An important fact mentioned by Dr Jubb is that the Hoylake cases had a common milk supply Further information required here is whether the *same horse* and man carried the milk, because stomoxys having a particular liking for warm horse blood would be carried any distance on a horse, even though occasionally disturbed by tail swishes —I am, Sir, yours faithfully,

J T C NASH,

County Medical Officer of Health

The Shirehouse Norwich Jan 9th 1915

THE MEDICAL SOCIETY OF LONDON

To the Editor of THE LANCET

SIR,—Owing to the war the usual programme for the second half of the session will not be issued, but postcards will be sent to Fellows from time to time giving details of the arrangements made

The meeting arranged for Jan 11th was not held On Jan 25th, at 8 30 P M, arrangements have been made to have an X ray evening, when Dr Ironside Bruce, Sir James Mackenzie Davidson, Dr F H Humphris, Dr Harrison Orton, Dr A Jordan, and others, will demonstrate and exhibit items of interest connected with the war On Feb 8th Sir Victor Horsley, F R S, will open a discussion on Gunshot Wounds of the Head

We are, Sir, yours faithfully,

GEORGE E GASK,

HERBERT FRENCH,

Honorary Secretaries

Chandos street Cavendish square W Jan 12th 1915 the President of University College Dublin the President of the Pharmaceutical Society and many leaders of the medical profession has been formed The Registrar of the Royal College of Physicians (Dr T Percy C Kirkpatrick) and the Secretary to the Council of the Royal College of Surgeons (Dr C M Benson), combine the offices of treasurer and secretary and subscriptions may be sent to either at the Royal College of Physicians Kildare-street, Dublin. A substantial sum of money has been already received

The Master of the Society of Apothecaries of London, in reply to a request published in the medical journals has received at the Apothecaries' Hall, Blackfriars, London E C many surgical instruments for distribution among Belgian practitioners, and these are still being generously presented

The Committee has already done much preliminary work, and its various steps have been reported weekly in *The Lancet* and the *British Medical Journal*, in both of which journals Dr Jacobs's appeal was published on Nov 21st But sight has not been lost of a larger object Sooner or later the rehabilitation of Belgium will be an honourable charge upon the countries saved by her courage No doubt the State will take control of large measures to this end, but there will be room for international action whereby the doctors and pharmacists all the world over can cooperate in aiding their Belgian colleagues to a re-establishment of their professional positions At the right time this Committee will be ready to take its share in such a movement

SUBSCRIPTIONS RECEIVED

The following subscriptions have been received up to Jan 5th, 1915.

THE GENERAL COMMITTEE (*continued*)—

Professor William Thorburn
Dr James Pearse, *Medical Officer of the National Insurance Commission (England)*
Dr Macdowel Cosgrave, *President of the Royal College of Physicians of Ireland*
Dr H Macnaughton-Jones
Professor Alfred Barrs
Sir George Hare Philipson, *Vice Chancellor of the University of Durham*
Dr A H F Barbour, *President of the Royal College of Physicians of Edinburgh*
Professor John Barlow, *President of the Royal Faculty of Physicians and Surgeons, Glasgow*
Professor Conway Dwyer, *President of the Royal College of Surgeons in Ireland*
Sir Anderson Critchett, Bart
Sir W Arbuthnot Lane, Bart
Sir William Milligan

Mr D M Watson, *President of the Pharmaceutical Society of Ireland*
Dr W K Hunter
Mr F P Sargeant
Mr W S Glyn Jones, M P
Mr J C Umney
Mr D Gilmour
Mr J P Gilmour
Mr W L Currie
Mr T Guthrie
Mr J Rutherford Hill
Sir T Barclay
Professor J Marnoch
Professor J M Munro Kerr.

THE OBJECTS OF THE FUND

The Committee was started in reply to an appeal from Belgium, brought by Professor C Jacobs of Brussels, who represented in moving terms the terrible position in which his colleagues and also the pharmacists in that gallant country were involved At the same time, the giving of assistance to the members of the medical and pharmaceutical professions and their families who are refugees among us is clearly a matter of urgency and a worthy object of subscriptions It was recognised at the outset that it would be impossible, while the German occupation lasted, to do more for the doctors and pharmacists in Belgium than to despatch certain packets of medical material with which the misery created by the wholesale destruction of laboratories and pharmacies might be relieved A start has been made in this direction, and packets will be sent regularly when it is known that they can reach their destinations without interference The position of the refugees of the two professions is in many instances utterly sad, and a large amount of money could be usefully expended to meet their immediate needs

The plight of the pharmacists of Belgium is as heartrending as the position of the medical men, and their present needs, as well as their eventual necessities, should appeal with peculiar force to the pharmaceutical community of Great Britain Much has been done already unofficially in the way of organising practical sympathy on behalf of those expatriated pharmacists who have taken refuge in this country, but the problems that are daily arising, together with the claims which will ultimately reveal themselves, can only be met successfully and in a manner worthy of the occasion by systematic cooperation on the lines suggested in this appeal. The President and Vice-President of the Pharmaceutical Society of Great Britain feel that British pharmacists will be proud to share the honour of repaying in part, the enormous debt of gratitude which Great Britain owes to Belgium for its heroic sacrifices

A comprehensive scheme is being organised under which an appeal will be made to all Scottish practitioners A large Committee is being formed from representatives of the Universities, the Royal Colleges of Physicians and Surgeons the Royal Faculty of Glasgow, and the pharmaceutical profession

In Ireland the Royal College of Physicians and the Royal College of Surgeons have already taken action A Committee including the Presidents of the Colleges,

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND

DURING the week ending Tuesday, Jan 12th, the subscriptions received to the Fund have been numerous, and a contribution of £112 2s 6d has been sent since through Dr Major Greenwood from the Brussels Medical Graduates Association

The directors of the British Milk Products Company have announced their intention of sending a portion of their takings by the sale of sanaphos for one month from Monday next to the Fund, guaranteeing that the contribution shall be not less than 150 guineas

Among those who have joined the General Committee since the last list of names was published may be mentioned Sir William Milligan, Sir Thomas Barclay, Professor Marnoch, and Professor Munro Kerr

A meeting of the Executive Committee was held on Thursday afternoon, Jan 7th, when the question of opening up communication with Belgium for the purpose of ministering to the wants of the Belgian doctors and pharmacists was discussed in the light of information from the United States In the United States work similar to that which the British Fund is doing has been started An American committee of medical men will operate through the International Commission for Relief in Belgium and will have packages, prepared by instrument makers and pharmaceutical houses of the United States, shipped for distribution in Belgium upon exactly the same method as the British Fund has adopted.

A meeting of the subcommittee empowered for the present to make emergency grants was held on Friday, Jan 8th, when Dr Clement Philippe attended to represent the Belgian Medical Society in London and placed before the subcommittee the details of various cases The grants were made A representative of Messrs Harrods, Limited, was present, and a guarantee was given to that firm for the supply of clothes of an agreed class to Belgian doctors whose names were submitted by Dr Philippe

A circular explaining the objects of the Fund, which has been widely distributed to the medical profession, will be found on page 153, and a leading article deals further with the matter this week

The subscriptions which have been received up to Tuesday evening last by Dr Des Vœux, in addition to £2654 previously acknowledged, and not including the subscriptions received in Dublin, are as follows —

For Subscriptions received this week see opposite page

possible intact. Bearing these facts in mind, and further, that although the man who is absent is receiving pay and allowances he is nevertheless bound to submit to, it may be, considerable loss of practice, the Committee suggest the following arrangements for three classes of practice.

Class 1.—Large towns where the question of mileage is not a very important consideration. Here it is suggested that an equal division of the remuneration should be agreed upon, this to apply both to private and insurance practice.

Class 2.—Towns with a considerable population but with a large amount of country work, necessarily involving the question of travelling expenses. It may be possible to ascertain these with more or less exactness, but as a general rule probably a division of all remuneration on the basis of three-eighths to the absentee and five-eighths to the man who is doing all the work and paying all the expenses is the nearest to equity.

Class 3.—Smaller centres or single-practice areas where the question of travelling expenses and consumption of time becomes still more important. (It is not desirable that a man should undertake the duties of a practice whose centre is perhaps ten miles from his own and the committee will do their utmost to provide locums in such cases. In such possibly a fractionally larger proportion should be allotted to the man who is doing the work.)

It should be noted with regard to the three classes of practice that the difference between, say, a town practice (Class 1) on the one hand and a town and country practice (Class 2) on the other, is not entirely one of geographical situation. Practices in large cities will in general offer no difficulty. They are town practices pure and simple. For practices in towns of moderate size, however, much will depend on the character of the town. In industrial burghs many practices will suitably be classed as town practices (Class 1), while in a market town of the same population all practices will probably be of the town and country class (Class 2). In the same town again some practices will belong to Class 1 and others to Class 2. Lastly, in many small towns where the bulk of the work lies in the surrounding country the town element may be practically non-existent, and the practice would fairly be counted in the country class (Class 3). Consideration of the facts and of local conditions can alone determine the correct point of view in doubtful cases.

The foregoing considerations are thought to be applicable both to private and insurance practice, including under private practice all fees for medical attendance, operations, midwifery and the like, and under insurance practice all capitation fees, mileage, and dispensing allowances, and other charges if any. The sum total of such amounts would be divided between absentee and deputy in the proportion of half and half, three-eighths and five-eighths and one-quarter and three-quarters according as the practice falls under Class 1, Class 2, or Class 3. In private practice the treatment of cash payments will be simple. As regards the rendering of accounts for work on behalf of absentees, these should be sent out by the deputy at the same time as he sends out his own, and it is suggested that they should be sent by "Dr A on behalf of Dr B, absent on duty with the King's Forces." The committee are confident that in insurance practice no deputy acting on behalf of a practitioner absent on war service will wittingly endeavour to secure the transfer of the absentee's patients to his own list. It is not necessary for a transfer to be made in order that attendance may be given. By the terms of the existing practitioners' agreements the position of the deputy is recognised and provision is made for his employment. In certain cases, however, insured persons on the lists of absentee doctors may themselves have already taken the initiative with a view to transfer. They may have given due notice of their desire to change their doctor. It appears that having done so they are at liberty to make a fresh choice, and that if they fail to be accepted they have the right to be assigned to a practitioner on the panel. It seems to the committee that it would be a proper course for the practitioner to whom such patients apply to accept them in trust for the absentee, sharing the capitation and other allowances on the principles above proposed and giving the patient the opportunity of being transferred back to his own doctor's list immediately on the latter's return from active service. It is necessary to recognise that proposed transfers may in some cases have nothing to do with the war. Such applications must be considered on their merits, and the decision will often be difficult. In any case of uncertainty the deputy will no doubt lean to generosity and accept the patient in trust for his absent colleague.

It was agreed that this statement should be sent for publication to the medical journals, and that it should be printed as a circular, copies of which can be had on application to the Convener at the Royal College of Physicians, Edinburgh. The committee expressed its satisfaction with the terms of the Director-General's circular, and the Convener was directed to convey its thanks to Sir Alfred Keogh, Director General of the Army Medical Department. Several communications with reference to it had been received, and the committee expressed the hope that full advantage would be taken of this provision, and that even if the individual himself was not benefited by an exchange he would facilitate it in the interests of his colleagues and of the public.

Reference was made at the meeting to the Order in Council applying Part II of the Medical Act, 1886, to Belgium, the outcome of which might be that Belgian doctors can legitimately practise in this country.

Voluntary Hospitals and Wounded Soldiers

The Council of the British Hospitals Association, 14, Victoria street, Westminster, S.W., have had under consideration the varying conditions under which the voluntary hospitals throughout Great Britain are receiving wounded soldiers for treatment. They point out that arrangements which the War Office has made with these institutions as to payment vary considerably, for instance, few, if any, of the hospitals in London have asked for any payment from the Government, whilst most of the provincial hospitals expect to be paid at rates which vary from 2*s* to 4*s* per patient per day. In these circumstances the Council are inviting the secretaries of voluntary hospitals to elicit the views of their committees as to whether an application should be made to the War Office to deal upon the basis of a uniform scale of payment with all the voluntary hospitals in which payment is desired. They understand that some such arrangement has been made in reference to the private hospitals provided by the British Red Cross Society and other similar organisations. The Council have also had under consideration the question as to whether an application should be made to the Inland Revenue authorities to remit the duty on rectified spirit used in hospitals in the making of tinctures, galenicals, &c. This matter has been referred to a small committee for further consideration and inquiry.

THE BRITISH RED CROSS SOCIETY.—In its summary of work accomplished during the week ending Jan 9th the British Red Cross Society states that the number of auxiliary home hospitals accepted by the War Office to date is 675 containing beds for 18,782, including 354 beds accepted during the past week. The following additional ambulance cars have been despatched: 25 ambulances to the British Ambulance Committee (French Red Cross), 11 ambulances, 1 lorry, and 1 motor cyclist to Boulogne, 1 ambulance and 1 soup kitchen to Dunkirk, 1 ambulance to Havre, and 2 to places in England. At the Netley Red Cross Hospital there have been during the week 231 British and 233 Indian sick and wounded. Two cases of tetanus have recovered and have been removed from isolation. Two concerts have been given during the week,

In the second list published in THE LANCET on Dec 19th, p 1441, for "Edward Murphy" there should be read "Edmond Murphy"

Subscriptions to the Irish Fund should be sent to the Royal College of Physicians of Ireland addressed to Dr T P C Kirkpatrick, Registrar of the College, and Dr C M Benson, secretary of the Royal College of Surgeons in Ireland, who are acting as honorary secretaries and treasurers to the Fund

THE APPEAL FOR SURGICAL INSTRUMENTS

The Master of the Society of Apothecaries begs to acknowledge with thanks the receipt of surgical instruments, &c, kindly contributed by the following gentlemen since the publication of the last list —

Dr Hugh R Smith South Hampstead, N W, Mr J D Staple, Bristol, Dr W R Reith, Erdington, Birmingham, and Dr Samuel Davidson, Kelso

THE Governor of Mauritius, in a telegram to the Secretary of State for the Colonies, received at the Colonial Office on Jan 8th, states that six cases of plague were reported during the past week, and the number of deaths was six

METROPOLITAN WATER BOARD AND MEDICAL ATTENDANCE—At the last meeting of this Board, held on Jan 8th, the works and stores committee submitted a report reminding the Board of its decision to provide gratuitous medical attendance for each workman excepted from the provisions of the National Insurance Act, 1911, and to pay each district medical officer appointed by the Board at the rate of 10s per annum in respect of each workman placed on his panel, subject to the approval of the committee, such fee to include attendance, medicine, and the provision of all certificates and reports desired by the Board The Board appointed 84 district medical officers, and as there was reason to be satisfied with the working of the arrangement the committee reported that they had decided to reappoint the whole of the district medical officers One officer had resigned his appointment and in his place Mr Robert Capes was appointed The reappointments, as in the first instance were for 12 months only, as from Jan 1st, in order to allow of the whole matter being brought automatically under annual review The regulations governing the scheme had been confirmed by the committee subject to the amendment of Regulation 6, which had been altered to provide that a district medical officer who examined an employee and considered him unfit for duty must forward his certificate to the district engineer within 24 hours of the examination

The War.

RETURN OF MEDICAL PRISONERS OF WAR

IT is announced that five released medical prisoners of war have arrived this week in London from Germany via Holland Three are officers of the Royal Army Medical Corps who were captured whilst tending British wounded, and the other two are civilian surgeons attached to the British Red Cross Society who were captured while tending Belgian wounded under the Belgian Red Cross Their names are as follows Captain C T Edmunds, R A M C, Captain E S B Hamilton, R A.M C, Lieutenant W S Danks, R A M C, and Dr L J Austin and Dr A R Elliott, temporarily attached to the 1st Belgian Red Cross Unit Graphic accounts of their experiences have appeared in various newspapers

MEDICO MILITARY PAPERS

An interesting article on "Frost bite" appears in another column this week from the pen of Mr A W Mayo Robson, who has had frequent opportunities of observing this condition in soldiers returned from the front We also print communications of medico military interest from Mr J Jackson Clarke, Mr F Newland Pedley, and Mr C F Constant

SCOTTISH MEDICAL SERVICE EMERGENCY COMMITTEE

A meeting of the Scottish Medical Service Emergency Committee was held on Jan 9th in the Royal College of Physicians of Edinburgh There were present the President of the Royal College of Physicians, the President of the Royal College of Surgeons, the Dean of the Faculty of Medicine, Aberdeen University, Dr J R Hamilton (Hawick), Dr J R Currie (Edinburgh), Dr J Adams (Glasgow), Dr J Stevens (Edinburgh), Dr G C Anderson (Methil), and Dr Norman Walker (Convener) Sir Donald MacAlister was present by invitation

The committee considered a draft statement which had been prepared by the subcommittee appointed at the last meeting, and approved of it in the following terms —

Statement by the Committee

From information in its possession the Scottish Medical Service Emergency Committee has reason to believe that some advice on the general principles which should be followed in making arrangements for the carrying on of the practices of those members of the profession who are serving with the King's Forces would be welcome. The available supply of locum tenents is so small that those whose duty keeps them at home must be depended upon to do the work of the absentee The Committee recognise that in many, perhaps most cases there are special circumstances with which it is not possible to deal in a general way There are, however certain broad principles of equity which are generally applicable The man who is with the forces has the stimulus of fresh and interesting work, and he has the satisfaction and honour of directly serving his country On the other hand, he may imperil the position he has established perhaps after many years of hard work. The man who remains to do the necessary work at home has a more prosaic duty He has to take on a large addition to work which may already be considerable and he has to do this without the prospect of its being of any lasting benefit to him, for it is the essence of these arrangements that they are only "for the period of the war and that the absentee when he returns shall find his practice as nearly as abroad during the war The car is of the British Red Cross standard dimensions and was built entirely by Messrs Argylls, Limited at Alexandria, Scotland The chassis is one of that firm's 15–30 h.p models with sleeve valve engine and four wheel diagonal braking system The tyres are extra large, and these with a silent rear axle worm, convey smooth running powers, while the comfort of the passengers is further ensured by rear three quarter elliptic springs and the use of Houdaille shock absorbers, which are attached to both front and rear axles The body consists of a wood frame, with canvas detachable curtains, and the ambulance accommodates four stretchers running on guides The body is so arranged that it can easily be made to accommodate comfortably 12 convalescents An electric roof lamp facilitates night work The executive committee consisted of Professor Rutherford Morison (chairman) Dr James Hudson (vice-chairman), Mr David Ranken (honorary secretary), Sir George Hare Philipson, Sir Thomas Oliver, Dr David Drummond, Dr W L Puxton, Dr Ranken Lyle, Dr S Whillis Dr G H Hume sen. Mr F Page, Dr C J Gibb, Dr E F Pratt Dr R Dagger, Dr J D Wardale, Dr Russell, Dr W S Fraser Dr A. C Burnell, Dr James Don Dr Ethel Williams Dr J T Dunlop, Dr J J Campbell, Dr A. Campbell and Dr H. Ll. Rutter The subscribers numbered 117 In presenting the ambulance Professor Morison said that great pains had been taken in the selection of the car after a most careful investigation of the conditions which such a car would have to meet. Colonel Gowans, commanding the First Northern General Hospital, in accepting the car, thanked the subscribers and paid a tribute to the judgment of the committee on their choice of a car, and hoped that at the end of the war it would be returned little the worse for wear for the use of the civilian sick of the district

THE DUCHESS OF WESTMINSTER'S HOSPITAL —The following is an extract from a letter received by a correspondent from one serving in the Duchess of Westminster's War Hospital —"Le Touquet par Etaples, well known for its first-rate golf links will in future be notable for the excellent war hospital which was organised shortly after the commencement of hostilities The patients are at the Casino which is an ideal place for a hospital, and the doctors and nurses are in the Hotel des Anglais, the use of both buildings has been given free The staff consists of a military commandant 4 surgeons, 2 physicians, an anæsthetist, an X ray officer, 4 dressers, 30 nurses, and 30 orderlies There are 270 beds, up to the end of 1914 about 800 patients had been admitted, chiefly cases of shell and bullet wounds and so-called 'frost bite, which is a misnomer There are a general inflammation of the feet due to long continued standing in wet boots in the rain sodden trenches producing discolouration and associated with anæsthesia or hyperæsthesia. The patients take a long time to recover, one of them was so bad that both feet were gangrenous with a definite line of demarcation, and were amputated He was a German prisoner There have been three cases of gas gangrene one of whom recovered By the irony of fate he was a German We have had three cases of tetanus two of whom died With regard to anti tetanic serum there seems little evidence as to its value, but everyone agrees that it ought to be given, as it does no harm, but with typhoid the case is very different At Wimereux 80 per cent of the cases had not been inoculated, of the remaining 20 per cent. nearly all were infected immediately after the inoculation—i e during the negative phase Two things forcibly strike me here First, the remarkable recoveries considering the horrible septic condition of many of the wounds There is no doubt that the more conservative one's surgery the more successful the results The number of aseptic cases is very small Secondly the happy way and cheerful endurance with which the men face their sufferings I have not heard a complaint or a groan from a patient since I have been here There are 'grousers' in almost every community but, thank heaven they are not to be found here"

THE DRUG HABIT AND MOBILISATION IN FRANCE —Our Paris Correspondent writes Dr Marcel Briand has lately been investigating the behaviour of the morphine takers in the French army Generally speaking while a few have not broken away from their demoralising habit many, being unable to obtain the drug, have perforce been compelled to become demorphinised and have thus been cured but not without considerable suffering The subjection to army discipline has also had a bracing moral effect, while in civil life the morphinomaniacs seek one another out and encourage each other in their vice There are at least two such now in the army who, coming from the same environment and locality, where they frequently associated in their habits and in their search for supplies of the drug on mobilisation, the one as an officer, the other in the ranks in the same regiment, now deceive one another as to their state by each pretending to have been cured long since, and while they still continue taking injections secretly, are rapidly lessening the dose to escape as quickly as possible from their tyrannical need, which becomes daily more hateful to them Their regiment has not yet been under fire, but there is every reason to hope that when this occurs the two men will be quite capable of adequately discharging their duty, which they could not have done a few weeks ago"

ULSTER VOLUNTEER FORCE HOSPITAL —This hospital which has been established in the Exhibition Hall, Belfast (granted by the Belfast City Corporation), for the reception of wounded soldiers and sailors, was opened on Jan 8th by Lady Carson. The Exhibition Hall has been transformed into a hospital with 80 beds, and 20 more beds have been provided at the Samaritan Hospital for Women (which for some time has been closed), where it is proposed to treat the more serious cases A neighbouring house (No 1, College Park East) has been generously placed at the disposal of the committee for use as a nurses' home The hospital is being lent to the War Office by the Ulster Volunteer Force, who will retain the ownership and be able to use it in whatever way they may deem proper after the war has been brought to a termination A large medical and nursing staff have been appointed

M.B DEGREE EXAMINATION AT BELFAST —A special examination for the M B degree was held in connexion with the Queen's University of Belfast last week, when 21 candidates were admitted to the degree A large number of these propose entering the Army Medical Service The degrees were conferred on Monday, Jan 11th.

Obituary.

SIR ROBERT MICHAEL SIMON, B A, M D CANTAB, M D BIRM., F.R C.P LOND,

CONSULTING PHYSICIAN TO THE GENERAL HOSPITAL, BIRMINGHAM
PROFESSOR OF THERAPEUTICS IN THE UNIVERSITY
OF BIRMINGHAM.

WITHIN a short period the medical profession of Birmingham has mourned the loss by death of three of its leading members, and some weeks ago a further loss was sustained by the death of Sir Robert Simon after a short illness

Born in 1850 Sir Robert Simon was a native of Nottingham He entered Caius College Cambridge, and graduated M B in 1876 and M D two years later He studied medicine at Guy's Hospital and in Berlin At first he settled in Manchester, where for three years he was honorary physician to the St Mary's Hospital for Women and Children In 1879 he became a Member of the Royal College of Physicians and was appointed assistant physician to the General Hospital, Birmingham, taking the place of the late Dr G A Gibson, who went to Edinburgh On the retirement of Sir Walter Foster (afterwards Lord Ilkeston) in 1891 Sir Robert Simon was elected honorary physician to the hospital, which position he held until April, 1914 His distinguished services to this institution rendered during 35 years were recognised last October, when an illuminated album was presented to him and a diamond tiara to Lady Simon An excellent portrait of Sir Robert Simon was at the same time presented and the members of the D'Oyley Carte Company playing at Southampton gave an entertainment

The total number of cases of stores sent abroad during the week was 479, of these 272 were despatched to Boulogne, 86 to Calais, and 67 to Havre, the balance representing small quantities sent to Dieppe, Wimereux, Dinant, and Dunkirk Seventy hospitals in this country were supplied with 379 cases of stores A large quantity of stores have been purchased to be sent out to Serbia and Montenegro The hospital ship *Queen Alexandra* has been busy conveying wounded from Dunkirk to Boulogne, and is now engaged in transporting stores

BRIGHTON MILITARY HOSPITALS VISIT OF THE KING AND QUEEN —Their Majesties the King and Queen paid a visit to Brighton on Saturday, Jan 9th, and made a tour of the several military hospitals which have already been established there Their Majesties' stay only lasted five hours in all, but in that short time they saw considerably over 2000 sick and wounded of the British and Indian Expeditionary Force, chatted with a great number of them, and imparted their sympathy and hopeful comfort The Indians are quartered at the Royal Pavilion and at a secondary school in the town, and at the former place, noted for its Oriental architecture, although there was no formal ceremony, the King expressed to the mayor and corporation his pleasure that the Royal Pavilion had been given up for the reception of his Indian warriors, adding, "It is not only these beautiful surroundings which the Indians will appreciate, but this lovely air is certain to help considerably in building them up again" The Royal inspection of the Indian General Hospital, as the Pavilion has been named, lasted one hour There were many very touching bedside scenes Their Majesties were filled with pity when in some cases Colonel Niel Campbell, the chief administrator, explained (where the patients were unable to do so for themselves) their battle record and the nature of their injuries But their Majesties' purpose was to hearten and console the wounded, and generally throughout their visit they maintained a cheerful manner, inspiring hope and a bright future on all sides Sir Walter Lawrence the War Office Commissioner, accompanied their Majesties during the tour, and he presented to the King and Queen Colonel Channer, Major Langston, and Major Waters, prominent members of the Indian Medical Service Another hour was spent at the secondary school, an annexe of the Indian General Hospital, where Colonel Sweeney is in charge, and after lunching with the Hon Sir Sidney Greville at Hove, their Majesties motored to the Second Eastern General Hospital in Dyke road, where there are about 800 British and Belgian wounded soldiers The administrators of the hospital, Lieutenant-Colonel Rooth, Captain Walker, and Lieutenant Ross, received the Royal visitors, and all the members of the medical staff were in attendance The King and Queen next visited St Mark's schools at Kemp Town and the Howard Home near by, two more military hospitals, and Mr John Howard, the generous donor of the institution bearing his name, was presented to the King and Queen and personally thanked for a gift of such great value Unfortunately, time did not permit of a visit being paid to the Royal Sussex County Hospital, where a good many wounded soldiers are being treated Everywhere their Majesties went they expressed not in a mere form of words their appreciation of all that they had seen and all that was being done for their wounded soldiers, and those who accompanied their Majesties from bed to bed can testify to the King and Queen's sympathy with their soldiers, showing how real and personal is the interest they are taking in the wounded

A MOTOR SURGICAL AND X RAY VAN —The January issue of *Cooper's Vehicle Journal* contains a full description with coloured plate and working drawing of a combined operating theatre and X ray wagon on a 5 ton Dennis chassis for use as near as possible to actual military operations, which has been devised by Sir William Collins with the help of the staff of that periodical The object of this collaboration was to harmonise in a practical fashion both medical and coachmaker's requirements The reasons for selecting this particular type of chassis are given but it is added that whatever type is chosen it should have an engine-driven lighting dynamo and lighting controls, while the suggestion is made that the theatre should be warmed by superheated steam generated by a burner suited for using petrol vapour or other fuel The body which is arranged to carry at least four persons besides the driver, is divided into three sections the front part for the driver, the middle part a light proof X ray room, 5 ft long, separated by sliding doors from the largest compartment, which is the actual theatre, 9 ft 6 in in length In setting out the theatre Mr G H Colt's brochure entitled "A Portable Operation Theatre" has been followed with much advantage So far as can be judged from studying the plans and descriptions, a very compact and workmanlike travelling theatre and X ray room has been designed One criticism suggests itself. It is a question whether the presence of such an allurement might not cause many operations to be done under temporary conditions that might more wisely be postponed till the patient could be sent back to a more permanent establishment That, however, is hardly a criticism of the van itself, and there will always be a residuum of cases in which promptitude in operating will outweigh all considerations tending towards postponement

Surgeon General Sir Arthur Sloggett, K C B, Director General, Army Medical Service, Overseas, accompanied by a staff officer recently inspected H S H the Prince of Monaco's model convalescent home at Monte Carlo for sick and wounded officers of British nationality Several patients have arrived at the home, which is in full working order

THE MEDICAL LITERATURE OF WAR —A correspondent writes —"Medical, nursing, and ambulance work in modern warfare has a literature of its own, which is swollen considerably after each campaign At least 25 volumes have been published relating to this aspect of the South African War, they range from official reports and hospital records to the memoranda of individual experiences This considerable list, however, is far outdone by the accumulation of medical literature which resulted from the war between France and Prussia in 1870 and 1871 Within 12 months of the cessation of hostilities more than 30 volumes containing in one form or another a medical history of the war had been published in the two lately belligerent countries The complete bibliography of the war, which itself fills a volume, shows that some 45 works in German and some 30 in French have been written exclusively around the experiences of the surgeons with the respective armies, the equipment and routine of the field hospitals, and the medical and ambulance service in the siege of Paris. The works range from brochures, priced at a franc or two or a few marks, up to voluminous and expensive treatises, these latter more especially from German pens Even in the 'eighties' books on the subject were still coming at intervals from the French and German presses and it was not until 1886 that there appeared the last of the eight volumes of the 'Sanitäts Bericht über die Deutschen Heere im Kriege gegen Frankreich' from the Prussian War Department. The French contributions are lighter but generally they are more intimate and vivacious 'Le Livret du Docteur,' by Dr A. Flamarion, Chevalier of the Legion of Honour for instance is really a loosely strung diary of the author's experiences from Sedan to Paris, and while he spares us nothing in his description of the horrible and the bizarre he lightens the narrative with touches of gaiety The principal English contribution to the medical literature of the Franco-Prussian War was in the form of the notes and recollections of Sir William MacCormac, which were published also in French and German In the United States the medical literature of war seems to be much slighter in character than in Europe Doubtless there were many ephemeral publications of the kind issued immediately after the Civil War, but a study of the list of printed books in the United States in 1912 only brought to light half a dozen works which recorded the nursing and surgical experiences of the war between North and South, while only one work, apparently, is extant dealing with this aspect of the Spanish American struggle"

NEWCASTLE PRACTITIONERS' WAR GIFT PRESENTATION OF A MOTOR AMBULANCE BY NEWCASTLE MEDICAL MEN —On Jan 8th at the Royal Victoria Infirmary, Newcastle on Tyne, a motor ambulance purchased by the medical men of the locality was formally presented to the First Northern General Hospital for service either locally or

Carey, Guy's Hospital Wahba Girgis St. Mary's Hospital Boris Abram Moishovich Gordon South Western Polytechnic and London Hospital Denis Paul Guilfoyle St. Bartholomew's Hospital William Rufus George Harris London Hospital Kenneth Charles Johnston Jones St Bartholomew's Hospital and Bedford School John Joseph Miles MacDonnell St. Thomas's Hospital Charles Moffatt Guy's Hospital George Murphy Birmingham University Elizabeth O Flynn School of Medicine for Women Arthur Arnold Osman and Adolphe Gladstone Millott Severn Guy's Hospital Yousif Ahmed Sunbul King's College Douglas Durrand Christian Thomson London Hospital Jacob Eliza van der Merwe and George William Wheldon Guy's Hospital and Frederick William Widgery, Royal Albert Memorial College

At the Second Professional Examination in Anatomy and Physiology held on Jan 7th, 9th, and 11th 51 candidates presented themselves, of whom 35 were approved and 16 were referred The following is a list of the successful candidates —

CENTENARIANS — Mrs Mary McCann, who retained her faculties till she died, passed away on Jan 9th in the Roman Catholic Home, Newry, on the 100th anniversary of her birthday —Mrs Lambert, of Edmonton, recently celebrated the 101st anniversary of her birthday

THE SUPPLY OF THYMOL —A shortage of this useful and powerful antiseptic has arisen owing to the fact that most of it was prepared from the raw material (ajowan seeds) by German makers These seeds are supplied for the most part from India, and we learn that the Imperial Institute authorities are taking steps to bring British manufacturers into communication with the Indian exporters of the seed with the view of extracting the oil in this country

THE SALE OF LAUDANUM —At the January meeting of the Council of the Pharmaceutical Society the following was adopted —

> That the policy to be advocated by the Council in regard to the sale of laudanum should be that when "laudanum" is asked for the 1914 preparation should be supplied and the poison book signed but where the 1898 preparation is demanded care should be taken to label it accordingly and the attention of the purchaser should be called to the fact that it is the 1898 preparation

RAINFALL IN THE NORTH OF IRELAND. —December, 1914, will long be remembered as the wettest month in Ulster for many years, while during it there was also an extraordinary prevalence of high winds, as well as a low average temperature Thus, at the famous golfing centre Newcastle co Down, there were 16 days on which rain fell and the total amount was 7 44 inches At Warrenpoint rain fell on 23 days in December to the extent of 8 03 inches as against 2 63 inches in December 1913 In the same district the total rainfall for 1914 was 37 44 inches as against 41 11 inches in 1913 In Newcastle the total rainfall for last year was 38 94 inches At Seaforde co Down the rainfall during 1914 was 38 95 inches as against 40 25 in 1913 at Letterkenny co Donegal it was 45 33 inches, at Markee co Sligo it was 46 58 inches while at Carna Connemara, in the west of Ireland it was [illegible] 10 inches At Cashel, Tipperary, there were 235 days with rain

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Meeting of the House of Lords

THE House of Lords met on three days last week Several matters arising out of the war were discussed An adjournment was then made until Feb 2nd, on which date the House of Commons reassembles

HOUSE OF LORDS

THURSDAY, JAN 7TH

Gifts of Motor Ambulances

Lord BALFOUR OF BURLEIGH asked His Majesty's Government whether it was the fact that with the consent of the War Office some motor ambulances had been provided by private benefaction for special brigades through the British Red Cross Association, whether, on such cars being landed in France, they had been taken possession of by the Army Service Corps and devoted to the general service of the Royal Army Medical Corps, and, if so, whether this course had the sanction and approval of the War Office His lordship went on to say that the facts as given to him from a private source were these Early in the war there was a great need for ambulance cars at the seat of military operations for the purpose of taking the wounded back to the base hospitals with as much speed as possible The fact that the demand exceeded the supply was one on which he did not care to throw stress He was told that this becoming known to the friends of some of the regiments concerned they got up subscriptions for providing ambulance cars for the special units in which they were interested He was informed by Mr Walter Long, whose son was in the Scots Greys, that the War Office was approached to get its consent that such a procedure in regard to this particular regiment should be adopted The War Office stated that individual units could not be given this privilege, but it would give its consent if the car was sent for the service of a particular brigade Accordingly the friends of the Scots Greys, the 12th Lancers, and the 20th Hussars, which made up one cavalry brigade, did provide ambulance motors for the service of that brigade He was told that in no single case had a car reached its destination. He was informed that every condition laid down by the War Office had been complied with and the cars were sent out to the British Red Cross Association He was not speaking on behalf of that organisation, but on behalf of those who supplied the cars Were the statements he had just made correct? If so, was it fair that the property of private persons, subscribed for under the sanction of the War Office for a definite purpose should be taken from them and applied to other purposes?

The LORD CHANCELLOR replied that he had looked into the matter A considerable number of motor ambulances had been provided by private benefactors, and in a great number of instances the donors had stipulated that the ambulance in question should be given to some particular unit or brigade The answer to these stipulations had invariably been that so far as possible the donors' wishes would be carried out, but it must be distinctly understood that any such gifts could only be accepted on the condition that they were available for the general service of the army Those ambulances which had been given for work with the Expeditionary Force had been so dispatched It was obvious however that the circumstances and difficulties of maintaining an army in the field made the special earmarking of certain vehicles to certain units only a practical impossibility A vehicle requiring only slight repairs must necessarily be replaced by an efficient one, and the damaged one when repaired must necessarily go into the general pool available for replacement wherever required It came to this that whilst an effort had been made to carry out the wishes of the donors the circumstances of the army made it impossible to carry them out in certain instances

Lord BALFOUR OF BURLEIGH remarked that the names of the units were painted on the cars concerned, and no communication had been made to any of the donors that the cars had been taken for the service of the Army Medical Corps. He was informed that one of the cars had not been paid for and the donor did not intend to do so until he got compensation

Inoculation against Typhoid

Lord TENTERDEN drew attention to the inoculation in His Majesty's Forces against typhoid, and asked His Majesty's Government for information as to whether inoculation was compulsory, and whether soldiers were involved in any penalties or disabilities if they refused to submit to inoculation He said that pressure was being put on soldiers to be to be hung in the board room of the General Hospital In the University of Birmingham he held for a short time the chair of Forensic Medicine, and for the last three years he was Professor of Therapeutics Besides the General Hospital appointment he was physician to the General Dispensary, consulting physician to the Dental Hospital, the Tewkesbury Hospital, the Nuneaton Hospital, Lichfield Cottage Hospital, and the Sutton Coldfield Dispensary He served a term as examiner in medicine at the University of Cambridge and as examiner in clinical medicine at the University of Birmingham He had also held the offices of President of the Birmingham Branch of the British Medical Association and of the Birmingham Medical Benevolent Society In 1910 he received the honour of knighthood in recognition of his professional position and of the services rendered to the city of Birmingham For 15 years he was a magistrate of the county of Warwick, and more recently had been a justice of the peace for Birmingham. His contributions to medical literature were few, the most important being the chapter on the diseases of workers in brass and copper for Oliver's "Dangerous Trades" An earlier paper on "Brass founders' Ague" had appeared in 1888 He was the author of "Lectures on the Treatment of Common Diseases of the Skin," based on his Ingleby lectures Two papers on "Cardiolysis" were published recently

Sir Robert Simon was a man of very considerable ability and possessed unusual clinical skill, which had gained for him a high reputation as a teacher and a large consulting practice in the Midlands As a physician he possessed broad and philosophic views of disease, and had the power of seizing at once the essential features of a case He was essentially a friendly man and easily won the confidence of his patients He was a good tempered colleague, considerate and helpful to his juniors The post of his house physician was much sought after, and his old residents would acknowledge how much they owe to his clinical experience and skill, to his friendly banter, and to the sense of responsibility and initiative which he tried to inculcate in them He had a great aptitude for games of skill, few were his equals at chess or bridge, and he was a good golfer Three years ago he had severe Menière's disease, which he faced with great courage Since then his health had not been very good, but it was hoped that the greater leisure resulting from his retirement from active hospital work would allow him to enjoy life for many years, and his death following a severe attack of influenza was a great shock to all his friends

Sir Robert Simon married in 1887 Emily Maud, a daughter of the late Mr W H Willans, of London and Seaton, who survives him with her daughter

ERNEST WILSON STOKER, F R C S IREL,

SURGEON TO OUT PATIENTS ST PAUL'S HOSPITAL, RED LION SQUARE W C

Dr Wilson Stoker belonged to the well known Irish family which has produced so many members of the medical profession His father and grand father were medical practitioners, and three out of four of his brothers follow the same calling He received his medical education at the Royal College of Surgeons in Ireland, where he graduated in 1888, and subsequently took the Fellowship He went through courses at Berlin and Vienna under Billroth and Politzer, and travelled extensively when a young man in various parts of the world He then came to London, and after holding the post of house surgeon at the Mount Vernon Hospital, settled in practice 17 years ago He recently took the house of his cousin, Mr George Stoker, C M G., in Hertford street, Mayfair, and attained considerable success in practice A personal friend writes "He loved his profession, and refused, notwithstanding his failing health from diabetes, to take a long rest, and died in harness, as he always wished to do, after a few hours' illness from pneumonia. The strain of the war, bringing attendance upon Red Cross hospitals and work to be done for absent friends serving at the Front, in addition to his personal work, proved to be too much for his strength. He had been a prominent athlete, having played Rugby football for Ireland in 1888–90, besides being a well known tennis player and a keen shot"

EDWARD IRWIN SCOTT, M D ST AND, L R C S IREL, L R C P IREL

Dr Edward Irwin Scott has died at Brighton from angina pectoris at the age of 68 years He was noted for his great thoughtfulness and kindness to all with whom he came in contact, rich and poor alike Dr Scott was formerly a member of the Hove town council, and was interested in local philanthropic societies as well as the National Society for the Prevention of Cruelty to Children and the Charity Organisation Society He was medical officer of the Brighton and Hove Dispensary for 25 years, and was ex president of the Irish Medical Schools and Graduates Association He formerly practised at Swatow

The funeral service was held at All Saints Church, Hove, when there was a large congregation of friends and patients

Fitzwilliams M D Ch M F R C S Price 6s net inoculated, even in cases in which they entertained conscientious objections to the operation Many cases had been brought to his notice where soldiers who refused had had their Christmas leave *stopped* He had seen many letters from soldiers in which they protested against the exercise of this pressure It was perfectly evident in spite of all official assurances in Parliament that inoculation was being made practically as compulsory as it could be

The Lord Chancellor replied that inoculation against enterical typhoid was not compulsory for any soldier There were special dangers at the front to men who were not inoculated, and the medical authorities were convinced of the benefits of inoculation Every effort was made to persuade men to be inoculated The only circular issued on the subject was that dated Oct 4th, 1914, and in it it was pointed out that this disease was a great danger on active service and that it was the duty of soldiers to guard against it, and if they did not do so they risked their chance of seeing active service because men who had adopted this precaution might be selected in their place It came to this that the medical authorities and the highest authorities were convinced that this inoculation was the very highest protection against enteric fever

Appointments.

Successful applicants for vacancies Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward to The Lancet *Office directed to the Sub-Editor, not later than 9 o clock on the Thursday morning of each week, such information for gratuitous publication*

HEALTH AND HOSPITALS IN HONG KONG

A REPORT on the *Blue-book of Hong Kong*, prepared by Mr Claud Severn, Colonial Secretary has been received at the Colonial Office and presented to Parliament From this it appears that at the Census taken on May 20th, 1911, the Chinese population amounted to 444,664 and the non-Chinese civil community numbered 12,075, making a total of 456 739, of whom 104,287 reside in the New Territories and in New Kowloon The estimated total population at the middle of 1913 was 489,114, but this included the New Territories, and as the birth and death figures do not include those from this area (with the exception of New Kowloon) the population for the purposes of calculating these rates is estimated at 398,520, of whom 21,740 were non Chinese The general birth rate for the year was 11·7 per 1000 among the Chinese community and 15·8 per 1000 among the non Chinese The general death rate was 21·75 per 1000 among the Chinese community and 10·9 among the non Chinese The number of deaths from malaria (290) showed a considerable decrease on the previous year (432) The deaths from plague numbered 386 as compared with 1768 in 1912 Small pox deaths numbered 84, all Chinese but two There were 2537 deaths from respiratory diseases among the Chinese, as compared with 2317 in 1912. Pulmonary tuberculosis and phthisis claimed 885 Chinese victims while other forms of tuberculosis represented an additional 384 deaths, making a total of 1269, or 15·5 per cent of the total deaths among that community Beri beri was responsible for 339 deaths as compared with 231 during 1912 and 320 in 1911

There can be very little doubt that the Chinese quarters generally are still in an overcrowded condition, and although the incidence of plague was light during 1913 there is reason to fear that the colony may not continue to be so fortunate The Sanitary Department are continuing their efforts to keep down the number of rats and to exclude them as far as possible from dwellings, while the scavenging service is also being strengthened with a view to reducing still further the available food supply of the rat population The mean shade temperature for the year at Kowloon (108 feet above mean sea level) was 71·9° the same as in 1912 and the ten preceding years The hottest month was July, with a mean temperature of 82·8° and the coldest January, with a mean temperature of 59·2° The temperature at the high levels of the Peak district is from 3° to 8° less than at Kowloon The total rainfall for the year was 83·73 inches, as compared with an average of 80·85 inches during the ten preceding years

The policy of the Government in controlling the importation and sale of morphine, compounds of opium, and cocaine was vigilantly maintained throughout the year, and the use of these drugs in the colony is now exclusively confined to medical purposes

To avoid the complete seclusion from friends and relatives which removal of Chinese plague patients to the Kennedy Town Infectious Diseases Hospital entailed, four district plague hospitals are now maintained by the Chinese in various parts of the colony These are under the management of the Chinese Public Dispensaries Committee which body also controls the eight dispensaries in existence including one for the boat population on a hulk in Causeway Bay The whole cost of maintenance is defrayed by voluntary subscription These institutions provide the Chinese with the services of doctors whose certificates will be accepted by the Registrar of Deaths, and with the services of interpreters who can assist the inmates of houses where cases of infectious disease have occurred Coolies are engaged and ambulances and vans are provided in order to remove cases of infectious diseases to the Infectious Diseases Hospital and dead bodies to the mortuary The dispensaries also receive sick infants and send them to one or other of the convents and arrange for the burial of dead infants Free advice and medicine are given and patients are attended at their houses

The new Kwong Wa Hospital for Chinese in the Kowloon Peninsula was opened in the autumn of 1911 It occupies a site of three acres and will ultimately provide accommodation for 210 patients The Hong Kong University is composed of three faculties (1) medicine (2) arts and (3) engineering and the medical faculty offers great facilities for the practice of medicine The anatomical laboratories were the gift of a Cantonese gentleman Mr Ng Li Hing There is a large staff of instructors in medicine and all the principal doctors of Hong Kong give lectures at the University

"WAR BREAD"

THE Germans have been issuing repeated warnings to the public to economise in the use of bread especially wheaten bread although the most frequently used bread in that country is black bread or rye bread and now a new bread called the "K" (Kriegs War) bread has been ordered to be consumed which contains a large admixture of potatoes With wheat steadily going up in price this has interest for ourselves There would no doubt be some grumbling at bread containing potatoes, but it is interesting to recall that in years gone by potatoes have been used in the making of bread by British bakers as a routine At certain times of stress in this country the rich have been exhorted to be sparing of the use of wheaten flour by mixing it with potatoes so that more might be available for the poor, and elaborate recipes for making bread with the proper proportions were printed in some of the old British favourite almanacks Potatoes yield in Germany 40 million tons to 8 million acres, whereas wheat only yields 4 million tons to 5 million acres, and rye 8 million tons to 14 million acres

ACCEPTABLE APPRECIATION

To the Editor of THE LANCET

MY DEAR EDITOR,—As I look back over this busy and eventful year, I realize to how great an extent the progress of the Department has depended upon the helpfulness of those who, while not in the Department or of it, have sympathised with its aims and have co-operated in its work Officially and personally I feel under obligation for the help you have given

With best wishes for the new year,

I am, yours cordially,

S S GOLDWATER, M D

Commissioner of Health, City of New York

Dec 31st, 1914

THE BRITISH TRADITION OF ENDURANCE

A TRADITION of endurance is the heritage of Englishmen It may prove of interest at a time when so much is being suffered in the trenches at the front and, be it remembered, in our North Sea Fleet during its anxious and strenuous vigil, to remind ourselves of some of the famous stories of what Britons have endured in the past A choice collection of horrors nobly faced is contained in the fine old "Narrative of Captain David Woodard and Four Seamen," which was published in 1804 with a curious appendix "containing narratives of various escapes from shipwrecks, under great hardships and abstinence, holding out a valuable Seaman's Guide, and the Importance of Union, Confidence and Perseverance in the midst of Distress." The case of Robert Scotney is so well authenticated as to compel belief This man a whaler, was picked up in the South Seas in the year 1803 He was the sole surviving occupant of a large boat, the crew of which had been swept away by a heavy sea which drenched his food He was alone at sea for 75 days, during which while steering a course for what he believed to be the nearest land he kept himself alive on 3½ lb of meat 3 lb of flour, 6 lb of bread, and two hogsheads of water, some whale-oil found at the bottoms of casks, and a small quantity of salt "He likewise emptied a medicine chest he had on board and got out of it some burning medicine which he found made his body a little comfortable and warm" He never had his clothes off and was almost constantly wet, yet he, humble sailor though he was, possessed the foresight and the moral courage to allowance himself daily while setting his sails, first for Tristan da Cunha which he missed and then for the Cape of Good Hope When found he had been for some days too feeble to visit his small store of food or to shift his helm and had kept alive with the help of tobacco of which he took an amazing quantity When taken on board "both his cheeks were swelled out amazingly with the ruinous quality he had in his mouth, and which he seemed to suck with convulsive agony" He had entirely lost the use of his limbs, he was pale and emaciated and it was the opinion of the surgeons that he could not have survived two days Scotney was a Lincolnshire man but we are not told whether he was strong or particularly enduring, or whether his heredity was in any way remarkable

Other survivors of hardship whose narratives are on record attained to respectable ages and must have been men of exceptional stamina Thus William Boys, for many years Lieutenant of Greenwich Hospital, who died in 1774 and fasted for 12 days annually in order to commemorate the hardships endured by him in 1727 must have been of a peculiarly sturdy type Cast away with 15 others in a boat in mid Atlantic he managed to survive 12 days without food or liquids, except a little rain water, some human blood and a few mouthfuls of human flesh Though seven or eight of the boat's crew died the survivors were restrained through horror and various other motives from becoming complete cannibals, and they carefully abstained from eating any parts of their dead comrades save the hearts and from drinking more than 4 pints of blood carefully measured, of four of them They might have been more cannibalistic but the point of the narrative is that for 12 days they abstained from human flesh almost entirely and were obviously debarred from

MEDICAL NOTES IN HISTORICAL MANUSCRIPTS

To the Editor of THE LANCET

SIR,—The papers of the Harley family include an excerpt from the *Newsletter* dated Whitehall, Oct 23rd 1688, which relates to the birth of James Francis Edward, Prince of Wales and son of James II, who was born on June 10th 1688 Some fear was entertained that the party in favour of the Prince of Orange (afterwards William III) would endeavour to impeach the legitimacy of the Prince of Wales, and the journal shows the quaint steps that were taken to forestall such an event

Yesterday the Lords Spiritual and Temporal now in town being summoned to attend His Majesty in the Council Chamber and the Queen Dowager with most of the Ladies and Gentlewomen who had been attending on the Queen s person during her being with child, or present when she was delivered of the Prince of Wales, and the physicians that had attended during that time, being all come into the Council Chamber, his Majesty declared to them the reason of their being called thither, which was as followeth —That by reason the malice of his Majesty s enemies had spread abroad some reports concerning the Prince of Wales as if he had not been his Majesty's but a 'suppose' child, and his Majesty expecting the Prince of Orange with the first easterly wind, when his Majesty intended to go in person at the head of the Army and not knowing what might happen, his Majesty was desirous to prevent any disturbances which might happen for the future concerning the Prince of Wales After which his Majesty desired the Queen Dowager to declare what she knew concerning the Queen being brought to bed Whereupon she declared that as soon as the King sent to her to come to the Queen's labour she came immediately and was with the Queen till she was delivered of a son Then the Marchioness of Powis and other ladies and gentlewomen, and after them my Lord Chancellor, Lord President, Earl of Middleton, Earl of Mulgrave, Earl of Feversham, and some others did declare upon Oath their knowledge touching the birth of the Prince of Wales, the sum whereof were as followeth —That the Queen being ill in the morning, after she was up, ordered a pallet bed to be got ready for her in the Bed chamber, but the pallet bed not being aired Mrs Dawson, who was then alone with her, persuaded her Majesty to let her own bed to be made ready again for her, which the Queen consenting to her bed was made and warmed with a warming pan of hot coals of fire, after which the Queen went to bed again, then the Queen Dowager and most of the persons above named being in the room the Queen had several pains which lasted for some time, after which the most part of Lords and Ladies there saw the midwife bring the child from between the clothes and laying it in a linen cloth gave it to Mrs La Badie and held up the after birth That Mrs La Badie carried immediately into the little bedchamber where all the Lords followed and saw her open the cloth, saying it was what they all desired a son And my Lord Chancellor said a steam came from it as from a new born child My Lord Middleton said it was foul as a new born child Sir Steven Fox said it was as a new born child and the Ladies declared some that they had seen the Queen milk her breasts during her being with child, others that they had frequently seen milk upon the Queen's smocks, and some that they had seen the Queen's belly during that time The Physicians declared that at the instance of the ladies they cut the navel string, from whence flowed lukewarm blood which they mixed with black cherry water and gave the child to prevent fits Mrs Pierce the laundress and wife to Pierce the chirurgeon declared upon oath that the Queen's linen during the time of lying in was as the linen of a child bed woman used to be, and the midwife deposed that she delivered the Queen of the Prince of Wales After all which the King himself was pleased to declare that besides that his Majesty had felt the child stirring in the Queen's belly about twenty times during her being with child, his Majesty as he had usually done at the birth of his other children had laid his hand upon the Queen s stomach during her being in labour to keep the child from coming back, and that he followed the child down with his hand till he could tell them it was coming into the world

I am, Sir, yours faithfully,

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed " To the Sub-Editor "

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed " To the Manager*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index and Title-page to Vol II of 1914 were given in THE LANCET of Dec 26th, 1914

VOLUMES AND CASES

VOLUMES for the second half of the year 1914 are now ready Bound in cloth, gilt lettered price 16s , carriage extra

Cases for binding the half year's numbers are also ready Cloth gilt lettered price 2s by post 2s 3d

To be obtained on application to the Manager accompanied by remittance

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423 Strand London W C are dealt with by them Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows —

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD	
One Year	..£1 1 0	One Year	...£1 5 0
Six Months	.. 0 12 6	Six Months	... 0 14 0
Three Months	.. 0 6 6	Three Months ...	... 0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch ") should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

TO COLONIAL AND FOREIGN SUBSCRIBERS

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS WILLIAM WOOD AND CO , 51, Fifth Avenue, New York, U S A.

other nourishment These old sufferers were curiously religious and strangely subordinate even when they turned into eaters of dead men and waited to eat their horrid ration after Captain Scurrion had been fed And it is this strong religious feeling and this sense of discipline which seems to have become part of the British tradition It emerges in innumerable letters from the front to-day, and is one of those assets of mind as dominant over body which differentiate the great from the ignoble races There is a similarity about these classic narratives of endurance which, though inspiring, renders repetition unnecessary We have cited two typical instances, and need not do more than mention the sufferings of Lieutenant Bligh, Captain Inglefield, Dean, Dominicus, Fellowes, and Kennedy, all of which were attested by numerous witnesses Among these heroic old sufferers one figure particularly interests us, that of the ship's surgeon, who seems always to have been of the boat's crew Among Boys's companions, for instance, was Thomas Scrimsour, surgeon, who lived at North Cray in Kent, and died at the age of 80 in 1784 Though he had been one of the first to be served in the shrinking and horror stricken anthropophagies of his comrades, he was noted through life as a pattern of "*probity and benevolence*" Character, indeed, seems never to have been wanting to the old adventurous medical men of the age that saw the foundation of the Empire and the final formation of the British type

VITAL STATISTICS OF BARBADOS

A REPORT prepared by Major J A. Burdon, C M G, Colonial Secretary of Barbados, states that the population of the colony on Dec 31st, 1913, was estimated to be 72,066 males, 101,293 females—total, 173,359 The birth rate per 1000 for the year was 31·9, as compared with 36 8 in 1912, and the death rate 21 3, as against 41·0 Illegitimate births numbered 3359, or 60 5 per cent of the total births The burials of children under a year old numbered 1173, giving a rate of 213 per 1000 births This shows a decrease of 1469 such burials, and a reduction of 203 in the rate per 1000 on the figures for 1912, which were abnormal The mean maximum temperature for the year was 83 2° F and the mean minimum 74 9° The average rainfall from 138 stations was 56 84 inches At the General Hospital, situated in Bridgetown, 3356 patients were admitted during the year, of whom 247 died, and 26,913 out-patients were treated At the Lazaretto there were 12 admissions, 1 discharge, and 11 deaths, leaving 120 inmates at the end of the year Compulsory segregation is not in force in the colony At the Lunatic Asylum the daily average number of patients was 399 The admissions numbered 132, the discharges 39, and the deaths 76

BRITISH SALVARSAN

THE British Board of Trade having granted a licence to Mr Henry S Wellcome for the use of the enemy patents, Messrs Burroughs, Wellcome, and Co are now manufacturing a chemical product which, after a biological test under arrangements approved by the Board, is issued under the name "Kharsivan" Brand Salvarsan "Kharsivan" is positively stated to be identical chemically, physically, and therapeutically with the salvarsan of German manufacture, and is employed in the same manner and dosage At the moment two strengths only are issued, 0 4 and 0 6 gramme, in hermetically sealed tubes, and supplies are limited That Messrs Burroughs, Wellcome, and Co should have been equal to the occasion, and that their scientific resources should have brought them to the prompt solution of the problem of manufacture is a matter upon which this enterprising firm may well be congratulated.

THE ETIOLOGY OF THE WAR

ONE of the best condensed summaries of the causes, predisposing as well as exciting of the war that we have seen is "Origins of the Great War, or the British Case," by John Kirkpatrick, M A LL D, Emeritus Professor of History, University of Edinburgh, published by Adam and Charles Black, Limited of London, price 1*d* The author divides the causes into (1) immediate, (2) indirect, (3) constitutional, and considers each class with remarkable lucidity and such method and order as one has a right to expect from a professor of history

BOISSELIERS' BELGIAN CHOCOLATE FUND

MESSRS Boisseliers, chocolate makers at Watford, are appealing to the public to buy 250 000 boxes of their excellent chocolates and thus provide £5000 for the Belgian sufferers About one-fifth of the total receipts of the sales are being given to H M the King of Belgium through the *Daily Telegraph* Shilling Fund, and the purchase of either one 5*s* box two 3*s* boxes, or four 1*s* 6*d* boxes means a contribution of 1*s* to help the Belgians

THE gentleman who found an unopened letter addressed to the Editor of THE LANCET in an omnibus, and who kindly and anonymously posted it to this office, is informed that his courtesy is much appreciated

MONDAY —10 A M., Dr Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards 12 noon, *Dr Bernstein: Pathological* Demonstration 2 P.M., Medical and Surgical Clinics. X Rays Mr D Armour: *Operations* Dr *Pritchard*: Bacterial Therapy Department. Mr B Harman and Mr Gibb: Diseases of the Eye.

TUESDAY —10 A.M. Dr Owen: Demonstration of Cases in Wards. 2 P.M., *12 noon* Mr T *Gray*: Demonstration of Fractures &c. Operations. Medical and Surgical Clinics X Rays. Mr Baldwin: Operations Dr Pernet: Dr Davis: Diseases of the Throat, *Nose* and *Ear* Diseases of the Skin

WEDNESDAY —10 A.M Dr Saunders: *Diseases of* Children. Dr Davis: Operations of the Throat, Nose, and Ear 11 A.M., Mr Souttar: Demonstration of Minor *Operations* 12 noon, Lecture —Mr Souttar Abdominal Diagnosis 2 P M Medical and Surgical Clinics. X Rays. Mr Pardoe: Operations. Dr Simson: *Diseases of Women.* Mr Gibb: Diseases of the Eye.

THURSDAY —9 A.M. Dr Bernstein: Bacterial Therapy Department. 12 noon Lecture:—Dr G Stewart: *Neurological* Cases. 2 P.M., Medical and Surgical Clinics X Rays. Mr D Armour: Operations Mr B Harman: Diseases of the Eye.

FRIDAY —9 A M Dr Simson: *Gynæcological* Operations. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards 12.15 P.M., Lecture:—Dr Bernstein: Applied Pathology 2 P M., Medical and Surgical Clinics. X Rays. Mr Baldwin: Operations. Dr Pernet: Dr Davis: Diseases of the Throat, Nose, and Ear *Diseases of the Skin.*

A Clinical Lecture.

"AGAINST HIS OWN BODY"

Delivered at St Bartholomew's Hospital on Jan 20th, 1915,

BY D'ARCY POWER, F R C S ENG ,

SURGEON TO THE HOSPITAL LIEUTENANT-COLONEL, R.A.M C (T)

GENTLEMEN,—The subject which I have chosen for my lecture to day would appear at first sight to be scarcely germane either to the time or the circumstances A little reflection, however, will show you that it is not so foreign as it seems It touches us politically and socially Politically, because we require the most perfect health possible in every man of the nation to enable him to undergo the wellnigh intolerable hardships of war Socially, because our losses are so great that the physique of the next generation must depend largely upon the continence of the young men of to day The subject, as you know, has already arrested the public attention in a remarkable manner, and henceforward you will be expected to give satisfactory reasons against the practice of fornication

If you ask me why I should lecture to you on so distasteful a subject I should reply, as the Lord John answered the Queen in that Italian Guazzo "An old, a grave, discreet man is fittest to discourse on such matters because he hath likely more experience, observed more, hath a more staid judgment, can better discern, resolve, discuss, advise, give better cautions and more solid precepts, better inform his auditors and by reason of his riper years sooner divert them" And that short excuse of Mercerus shall be mine "Si male locata est opera scribendo, ne ipsi locent in legendo" ("If I have spent my time ill to write, let them not be so idle as to read") But I am persuaded it is not so ill spent I ought not to excuse or repent myself of this subject on which many grave and worthy men have written whole volumes

I may say at the outset that the moral aspect of the question does not concern us directly and may safely be left in better hands than mine I would express my belief, however, that our present standard of sexual morality is much too low, although there is some evidence that it is improving with the spread of education To day at any rate I am concerned with the medical and eugenic sides of the question

THE PHYSIOLOGICAL ASPECT

We may start at once with the broad statement that fornication is absolutely unnecessary There is a widespread belief amongst many classes that sexual connexion is necessary for a young and healthy man Such a belief is physiologically incorrect It no more represents the truth than that other belief which long held sway, but is now fortunately exploded that no man could attain a healthy old age unless he "purged his reins and cleared his head by getting drunk at least once a month some said every fortnight Both suggestions originated with egotistic hedonists and were promulgated by those who were glad of an excuse to cloak their vices

Virility depends amongst other things upon the internal secretion of the testes which as you well know, is produced continuously, is reabsorbed into the blood, and is not excreted The semen or external secretion of the testes is formed in a manner similar to many other glandular secretions in the body It is stored up in the vesiculæ seminales, and if it is not required a great part is reabsorbed whilst the rest is excreted from time to time by a purely involuntary process The whole is a reflex action, and it is no more necessary to stimulate the vesiculæ seminales to contract than it is necessary to hawk and spit when saliva fills the mouth Occasional nocturnal emissions are natural and unavoidable If they are too numerous it is an indication that the man is thinking too much about sexual matters or that his general health is disturbed Nature is quite able to take care of herself in regard to the seminal secretion, and it is wholly unnecessary to resort to fornication to help her

You may safely assure any young man who asks your advice that fornication is a dangerous and unnecessary expedient, and you may further warn him that if he once begins it will be extremely hard to become continent again, whilst if he remains chaste the sexual appetite will remain dormant without in any way deteriorating In the end, too, he will be healthier, he will be more likely to marry for he will have a better opinion of women, he will have a happier married life, healthier children, and he will be free from the remote and often painful effects of those diseases which are known as venereal You may also assure him that fornication is no more an evidence of manliness than is smoking or drinking All three are the false ideals of youth and a bygone age Who of you did not think at school that it was a manly thing to smoke? Did not the lower classes endeavour to express the summum bonum of aristocracy when they said that such a one was "as drunk as a lord" Lapse of time has changed our ideals in both cases, and we know that manliness connotes very different attributes

Promiscuous intercourse degrades immediately by causing loss of self respect "Post coitum omne animal triste,' said Aristotle, and the more introspective pass through a purgatory which is out of all proportion to the satisfaction they have gained, the pain being partly regret for their folly and partly fear for the possible consequences This loss of self respect would be bad for the community if it was limited to the man, it is made ten times worse by the fact that it is shared by the woman and often drives her to very desperate courses Much has been written about the mentality of the prostitute, public as well as clandestine and it is agreed that whatever her physical attributes may be she differs widely from the average type of woman in the race to which she belongs In Europe she is often a sexual degenerate in spite of the highest social gifts, or she may be the most degraded of all animals like the woman who earned £30 a week by receiving 40–50 men a day Consort with such persons does much to destroy happiness in subsequent married life even if the husband has remained free from disease The sexual instincts of the prostitute are directed towards the gratification of lust or the acquisition of money those of the healthy minded woman so far as they exist at all before marriage, are towards motherhood the means being secondary and ill understood Indeed they were well expressed by the little girl who when asked what she was going to do when she grew up replied boldly that she was going to get married, have a baby, and then

more adequately but with less blasphemy. There is very little doubt that with more to talk about and a wider range of interests the dirty story will suffer a similar eclipse. Pornographic literature already finds fewer adherents, whilst, thanks to the admirable writings of such men as Anatole France, the cult of the old fashioned "French novel" and its "realistic" successor is dwindling rather than extending.

Were I asked in what way the State could best help to stop the spread of venereal disease I should answer without hesitation, Put the law against solicitation into active operation. At present it is a dead letter, and the streets of our large towns are a disgrace to the community. The women who frequent them must be well known to the police, for they may be seen day after day in the same streets. They will certainly continue their trade, but the men will then have to look for them, and many a youth will be protected from temptation. Knowledge, too is a powerful help. The physiology of the generative system is no more a mystery than the physiology of digestion or respiration, and there is no reason why it should not be explained in a scientific manner as a part of a course of biology. Let the women teach the women—there are plenty of well taught women nowadays who are fully equal to the task—and let the men instruct the men. The teachers themselves must be carefully chosen not only for their knowledge but for their general attainments, which should be sufficient to put their facts in proper focus.

TREATMENT

If, as unfortunately happens only too often, a man finds that he is infected with venereal disease, he should be taught that in his own interests as well as in those of the State he ought to go at once to a doctor. Every day that he delays lengthens the duration of his cure and may even prevent it entirely. Quacks and unqualified practitioners should be carefully avoided. They may have empirical knowledge, but they lack the scientific basis which every qualified man must have in some degree. Their object is to obtain as much money as possible, and they consequently prolong the cure and work upon the fears of their unfortunate clients, indeed, of all quacks the unqualified specialist in the treatment of venereal diseases has the worst reputation. The doctor, on his side, must not assume a repellent attitude. It is his business to cure, not to moralise, and to remember that the diseases run on the same lines as any other infective disorder. He must be especially careful to make a correct diagnosis especially in syphilis, where immediate treatment alone holds out a prospect of cure. For this purpose he must avail himself of scientific tests and must not rely solely upon clinical diagnosis. He should warn his patient from the outset of the particular dangers which are likely to arise and of the manner in which the diseases are spread. Above all he must point out the necessity for patience, since it is only by a prolonged course of treatment that a real cure can be effected. We have now long passed the stage when the disappearance of symptoms and signs was thought to be identical with eradication of the disease, and we have learnt that the worst effects have followed a conscientious but insufficient treatment. By these means you will gain the confidence of the patient and when you have gained his confidence the battle is half won. He will follow your advice and if he has come early enough you can accompany him well on the road to complete cure.

THE BLACK (PIGMENTED) APPENDIX[1]

BY WILLIAM HENRY BATTLE, F R C.S ENG,

SURGEON TO ST THOMAS'S HOSPITAL.

IN THE LANCET of July 19th, 1913, p 135,[2] I described a series of four cases in which a very unusual amount of pigmentation of the mucous membrane of the appendix was found after its removal for disease. Three of them were sketched; and I am able to produce the illustrations for the inspection of the section, the fourth appendix was mounted by Mr Shattock and is also shown. It differs from the others in the fact that there has been a great destruction of tissue towards the distal extremity.

With the exception of the case of extensive pigmentation of the large bowel, due to lead deposit, described by Dr G Newton Pitt,[3] I did not know of any similar appearance at that time. Recently, however, the subject of pigmentation of the bowel has been referred to by Sir J Bland-Sutton,[4] who found a very blackened state of the mucous membrane of the bowel in a woman suffering from obstruction due to cancerous growth of the large intestine. The cause of this pigmentation could not be ascertained, for the patient recovered. He refers in that address to an article by Dr Ludwig Pick[5] (which had escaped my notice) in which Dr Pick refers to two cases of pigmentation found in English publications (besides that by Dr Pitt), both of which were caused by the deposit of mercury in the tissues. 1. The case (described by Dr C J Williams) of a woman, aged 74[6], who had taken mercury regularly for 43 years. Here the submucous tissue of the large intestine from the ileo cæcal valve to the rectum was mottled like the skin on a toad's back. The patient had rectal prolapse before death; and the mucous membrane was seen to be deeply pigmented when extruded. 2. The case of a man, aged 64,[7] who had been under treatment for syphilis. He presented a similar pigmentation of the large bowel dependent on a deposit of mercury in the mucous membrane. In this case, which was described by Dr H D Rolleston, there was no evidence of pigmentation during life.

The contribution to the subject which I wish to make now consists of two cases of marked pigmentation of the appendix met with in women of different ages and circumstances. Their residences were far apart in Berkshire and Worcestershire, whilst of the four other instances already published three came from inside London and one from Kent. The cause of the phenomena must therefore be very widely distributed.

CASE 1.—The patient was an unmarried lady aged 48, who was seen in consultation with Dr L M Guilding on April 30th 1914. The medical history was a long one. Since the age of 13 she had been delicate and for years past constantly under medical treatment. Since the age of 21 she had always suffered from constipation, and the bowels had not acted without the use of purgatives. She had complained of indigestion for years, sometimes worse and sometimes better, of late years she had of necessity been very careful as regards her diet. In 1899 the cervix uteri was divided for dysmenorrhœa. In 1900 she had symptoms of kill her husband that she might have the child all to herself

Venereal Disease

If these were the only arguments against fornication we might well be contented to deal with the whole matter privately, as we have to deal with other filthy practices which merely concern the individual We should be neither better nor worse off than in the pagan times when philosophers wrote and argued against it in vain There is now an added danger of catching and transmitting disease This danger is very great, for in the year 1908 no less than 1959 prostitutes examined in Berlin were found to be diseased out of a total of 2944, whilst in Cologne in the same year only 247 were found healthy out of 600 Even the unaffected women were only relatively healthy and were not capable of infecting at the particular time they were examined Sooner or later all become diseased A Wassermann test proves that prostitutes are immune to syphilis because they already have it, and they are sterile as a result of inflammatory conditions associated with gonorrhœal infection Every man, therefore, who practises fornication runs a risk almost amounting to a certainty that he will get gonorrhœa or syphilis or both. Either or both diseases may follow a single lapse, and may be productive of life-long misery to himself, to the woman who is unfortunate enough to become his wife, and to the children of the marriage Through him the State, too, may suffer a grievous injury

Of the three diseases which can be caught from fornication—viz., soft sores, gonorrhœa, and syphilis—I have told you repeatedly that soft sores are neither more nor less than poisoned wounds and must be treated as such Their danger lies in the fact that they may be associated with a coincident syphilitic infection, masking its existence and causing active treatment to be unduly postponed

Gonorrhœa is a more serious disease than it is usually supposed to be It is serious to the individual during the acute stage by incapacitating him from work, later by crippling him from joint disease It is very difficult to cure, and if a stricture results it may shorten his life by causing retention of urine, cystitis, and disease of the kidneys Because of the difficulty of cure a man may give the disease to any healthy woman he marries She may thus become a permanent invalid, and may remain sterile as a result of the inflammation from which she has suffered, although in many cases the sterility is caused by the double epididymitis of which the husband has been the subject Children born whilst the mother is still uncured frequently have such a severe purulent inflammation of the eyes that the sight is impaired or may be completely lost The State, therefore, is greatly damaged by the gonococcal infection of the family, it loses the services of two generations either wholly or in part from a cause which is easily preventable

Syphilis is even more harmful both to the family and the State It often paralyses and lands its victims in an asylum with the most incurable of mental disorders, it predisposes to tubercle and cancer, and it shortens the expectation of life Unfortunately, it does not render the man sterile, as often happens in gonorrhœa, and the disease is transmitted to the children They may either be born dead, or those who survive may suffer from serious illnesses which leave them with lasting evidence of their father's incontinence as well as a depression of their natural physical and mental activity Syphilis has the farther disadvantage as a disease because there are periods when it is acutely infectious, and during these stages a man may infect his nearest and best friends in the most innocent manner, as by kissing or using in common a pipe or a glass

It must be clearly understood that these diseases are not contracted only from mercenary prostitutes—the ordinary street walker They are equally, or perhaps more, likely to be obtained from the very dangerous class who are known as clandestine, or occasional, harlots These women are much more ignorant in sexual matters than their more hardened sisters A gonococcal infection to them is merely an attack of "the whites," and the initial manifestation of syphilis is only "a boil" They do not know that they are ill, and they do not consequently seek advice to be cured

The Question of Prevention

The risks attending fornication, therefore, are very great, but they can be absolutely avoided by continence Much rests with the individual, though he ought to be helped by the State, whilst as members of the medical profession I conceive it to be part of our duty both to the individual and to the State to teach the elements of sexual physiology, and by so doing to diminish the diseases which cause so much damage

A healthy minded man does not become unchaste without a struggle, and when he has been warned of the risks he usually has the sense to look forward and not imperil his future health and happiness His natural modesty comes to his assistance, and he neither goes out of his way to look for a prostitute nor does he deliberately endeavour to seduce a virgin Some day, however he takes a little too much alcohol He does no get drunk, but he takes enough to lower his self control He is "picked up," as he will tell you by some loose woman on his way home, and from that evening he dates his downfall The temptation acts with especial force at the presen time, when the young men of the country ar separated from the good influences of home, and ar herded in camps with many thousands of companions of their own age The result is already beginning to show itself, and in some places more than in others It behoves everyone, therefore, who is in a position of authority to set an example of probity in sexual matters They should remember that venereal disease and the illnesses which result directly from them are very common causes of invaliding men out of the army, that at the present time every soldier is needed in the best of health and that it is of vital importance that preventable wastage should be prevented

It goes without saying that a young man who is happily engaged to marry a sensible girl of his own age and station in life is not so likely to yield to temptation as his less fortunate comrade He has the satisfaction of thinking that if she is willing to wait for him he can exercise equal restraint It is needless, too, to point out that the less a man concentrates his thoughts upon his sexual appetite the less it will trouble him The time is fast coming when it will be thought as bad form to tell a "smutty" story as it now is to swear We have it on excellent authority that our army swore terribly in Flanders, and our fathers have told us how prevalent was the habit even as late as the Regency period and the early Victorian days in England The spread of education, bringing with it a larger vocabulary, has enabled us to express our feelings the chemist for examination, but the result of examination for iron is negative, there appears to be very little in them

The question of the influence of roller milling in the causation of appendicitis is one which has interested me for some years Facts are accumulating to show that it is a serious factor, but this is not the occasion on which to consider it There is, however, very little doubt that in addition to the small sharp particles which result from the disintegration of the fluting of the rollers, and which sometimes cause localised ulceration of the mucous membrane, there is a considerable amount of "iron dust," which is given out in such quantities that in certain individuals it can produce an actual blackening of the mucous membrane over extensive portions of the large bowel This pigmentation is more extensive than could be produced by blood extravasations, and is more uniformly diffused.

Harley-street W

THE THEORY OF SALICYLATE THERAPY IN RHEUMATIC INFECTION

BY REGINALD MILLER M D LOND, M R C P LOND,

PHYSICIAN TO OUT PATIENTS AND LECTURER IN PHARMACOLOGY, ST MARY'S HOSPITAL PHYSICIAN PADDINGTON GREEN CHILDREN'S HOSPITAL.

ANY theory formulated to explain the action of the salicylate group of drugs in acute rheumatism has one great difficulty to overcome It is briefly this In some rheumatic manifestations, notably arthritis, salicylate is so successful in its action as to suggest strongly that the drug has an inhibitory power over the activity of the infecting organism, while in others, particularly chorea and carditis, such a power is by no means obvious It is this so called "selective" action of salicylate on the various manifestations of rheumatism which is responsible for the variety of views held upon its method of action

In a recent paper[1] I studied some of the practical objections which have been urged against the use of salicylate as a "specific" remedy in acute rheumatism, but purposely refrained from discussing the truth of the theory on which it is based Here it is intended to support this "specific' theory, using the word ' specific" as implying that the drug has the power of diminishing the activity of the rheumatic infection, the argument adopted being that this theory becomes acceptable when, but only when, the method by which the rheumatic infection produces its various results is properly understood

Modus Operandi of Rheumatic Infection

The modern view of rheumatism is that it is due to an infection by a particular type of micro organism This can be supported on strong clinical grounds as well as by the results of bacteriological research which are still unaccepted by some authorities How this infecting organism produces its results has been made clear by the histo pathological researches of Coombs,[2] supplementing earlier work of Poynton and Paine and others He finds evidence that rheumatic infection is a bacteriæmia which results in three sets of tissue changes 1 Interstitial inflammatory changes of a peculiar and characteristic type in the organs attacked by the infection 2 Parenchymatous toxic changes from toxins produced from foci of infection either local or distant These changes reach their maximum significance where important tissues, such as the cerebral cortex or myocardium, are involved 3 Sclerotic changes connected with healing processes

Modus Operandi of Salicylate Treatment

It is evident that a drug possessed of the power of diminishing the activity of the rheumatic infection could not control these three sets of tissue changes with equal success 1 The inflammatory processes should be well under the control of an antirheumatic drug Assuming that the foci of infection were open to the drug circulating, its only limitations would be concerned with the virulence of the infection compared with the amount of the drug which could operate 2 The toxic parenchymatous changes, on the other hand, could not be under the direct control of the drug All that such a remedy could do here would be to cut short the supply of toxin at its sources, and thus prevent further damage 3 The sclerotic changes obviously cannot be influenced by an antirheumatic drug, and need not be further discussed

Clinically, then, salicylate, if possessed of a specific antirheumatic power, would control such rheumatic manifestations and symptoms as are dependent upon active inflammatory processes, but could only indirectly influence those dependent upon toxic parenchymatous changes I must now review the chief rheumatic manifestations, attempting to show that their reaction to salicylate conforms to this theory

Arthritis—The histological changes here are those of acute inflammation of the infected tissues within and around the joint Toxic parenchymatous changes are of minimal importance here, as there are no "noble tissues" whose degeneration might produce symptoms Under salicylate treatment there is a rapid subsidence of the local signs of inflammation together with a fall in general temperature This last is of special importance, particularly when it is remembered that such a fall in temperature is not produced so markedly nor so constantly in any other infection, and therefore cannot be due merely to the slight general vaso dilatation caused by salicylate A fall in temperature, occurring in conjunction with local amelioration and general constitutional improvement, is generally held to be the best evidence of diminished bacterial activity, and it is certainly difficult to account for the success of salicylate in the treatment of rheumatic arthritis except by allowing a specific antirheumatic action to the drug Another result confirms this view—namely, the way in which salicylate puts a stop to the development of arthritis in other joints which is so characteristic of the untreated infection

There is one limitation to the successful action of salicylate on rheumatic arthritis—that concerned with large effusions These may remain for a week or so before disappearing, even though the temperature has fallen and the other local signs have cleared up The fluid obtained, however, from a joint at this stage will be found not only to be sterile but to show practically no cells It shows, that is to say, no signs of bacterial activity, and it is evident that no antirheumatic drug could have an action upon such an effusion Its absorption is necessarily and mainly a matter of time

The action of salicylate on rheumatic arthritis shows well how the drug successfully controls such symptoms as depend upon bacterial activity, and inflammation of subacute character which were said to have had their origin in the right ovary and broad ligament Ever since the operation in 1899 she had had occasional attacks of pain and tenderness in the right iliac fossa, during which there had sometimes been vomiting In some of these attacks the pain was more in the upper part of the abdomen In 1904 she had an attack which was described as acute ovaritis on the right side, and had felt "uncomfortable" on that side since In 1911 she had an attack of "neuritis" in the right arm, which lasted nearly the whole year She was also under treatment for colitis and a toxic condition towards the end of that year and this was resumed for varying periods during 1912 and 1913, finishing in March, 1914 Before 1914 the right iliac fossa was not much in evidence, after the beginning of that year she had four attacks of pain and tenderness in that region, one of them being severe and accompanied with a rise of temperature and other signs of inflammation, but without vomiting She had become thin, sallow, and pale with a persisting tenderness over the appendix region The diagnosis previously given was that of a chronic appendicitis with probable ileal kink and chronic intestinal stasis

An examination by the X rays after a bismuth meal had been carried out and the following points were established 1 A delay in the passage of the bismuth through the cæcum 2 The ascending colon and transverse colon were distinctly dropped, and there was considerable stasis in the passage of the bismuth all along the large bowel 3 Considerable loss of tone in the rectum Here the bismuth lodged and distended the part, having to be evacuated by means of enemata

When I saw her in April I agreed with the diagnosis of subacute inflammation of the appendix, with want of muscular power in the large bowel and rectum She was rather feeble delicate, and "tired looking" The abdomen was slightly distended, generally tympanitic, and tenderness was complained of on examination of the right iliac fossa Operation was performed on May 2nd 1914 The appendix was about 3¼ inches long, slightly adherent at the tip The meso-appendix was shortened at one point, and there were chronic catarrhal changes with submucous fibrosis The mucous membrane was of a uniform brownish black colour, due to the deposit of pigment From the abrupt termination of this at the place where the appendix had been cut off it was quite evident that a similar condition extended into the cæcum The intestine did not give any evidence of this on inspection The right ovary was atrophied and the tube normal A membrane united the transverse and ascending portion of the colon at the hepatic flexure, making a somewhat sharp and fixed bend It appears to have been derived from the right margin of the omentum This membrane was divided, and a few vessels in it were ligatured. The cæcum was somewhat larger than usual with a tendency to drop towards the pelvis The ovary and tube were removed Recovery was uneventful

CASE 2 —This case was also met with last year On May 17th, 1914, I operated for Dr A. A Brockatt, of Malvern, on a young unmarried lady, aged 27, who gave the following history Five months before she had had an attack of appendicitis which lasted five days Two months before she had suffered from a second attack which lasted seven days There had been some occasional pain between the attacks but otherwise she had not been ill She always suffered from constipation Nothing abnormal was felt on examination, but there was some tenderness in the right iliac fossa and she stated that pain had been present there the previous evening The temperature was normal The appendix when removed was found to be 5½ inches in length bulbous and red at the top from recent inflammation The meso appendix was shortened at one point The mucous membrane was pigmented the shade deepening in intensity to the line of section where it was quite black. There was submucous fibrosis No adhesions were present No other abnormal condition was found This appendix was lost

These two cases, together with those already published, make a series of six which present some common features In the first place there was an extensive brownish black pigmentation evidently not limited to the appendix but spreading an unknown distance into the large bowel The patients were all of the female sex (aged 27, 30, 32, 43, 48, and 48) and in each there was a history of constipation of long standing, which amounted to intestinal stasis in more than one of them according to their medical attendants It would appear as if in some the difficulty with the bowels had led to a secondary inflammatory affection of the appendix Operation in each was for the relief of pain caused by this The pigmentation was found on examination of the removed appendix, and in only one was there any appearance of darkening of the bowel as examined from the operation incision. Microscopical examination showed the deposit to be both in and between the cells of the mucous membrane (Shattock)

Chemical analysis of the first three specimens by Mr Le Sueur showed that the pigmentation was produced by a deposit of iron, the exact combination not being defined owing to the small quantity of material available There was no bismuth, lead, or mercury present In only one patient was there any history of the taking of iron medicine, and she had been given the compound syrup of the hypophosphites (¾ gm ferri hypophosph) There is very little, if any, tendency to pigmentation of intestine by iron given in the form of medicine, otherwise the condition would be frequently met with in the post mortem room And we should have had many references to it in our medical publications

From the fact that I have met with these six cases within a comparatively short period there is a probability that it is more common and widely spread than we have suspected The question arises as to the source from which the iron has been obtained There can, I think, be very little doubt that it is derived from wheat flour prepared by the iron rollers which are used in the modern process of milling These rollers are fluted, and the fluting wears down somewhat quickly, and although measures are taken to prevent iron particles from entering the mill none are taken to remove the iron dust and small particles which come away as a result of the rubbing of one roller against the other The method of grinding with iron rollers was once applied to the manufacture of light coloured pigments for painting walls, but had to be given up because of the brown patches which appeared on the walls to which such paint was applied The rollers wear away more quickly in the grinding of wheat, especially that grown abroad, which is harder than ours, than in the preparation of pigment Chemical examination of a quantity of best flour has shown the presence of an abnormal amount of iron, although none could be separated from the flour by means of a *magnet*

I have already alluded to the fact that no measures are taken to extract the iron from flour prepared by these rollers, therefore there is a considerable quantity being taken into the alimentary canal by the population at large It is very probable that the increased amount of troublesome constipation of recent years, which in some cases is described as "stasis" and ascribed to a kink of the bowel, is due to this cause, kinks possessing a clinical value are in my experience very rare It would be interesting to know from the experience of the physicians whether anæmia is any less common than it used to be

I think that it may be possible that fæcal concretions are helped to form by this ingredient of flour, but it is not possible to say much on the subject I have submitted several concretions to an increase in the daily dose of salicylate to, say, 100–120 gr.

In more severe cardiac cases, where there is evidence of advanced myocardial degeneration, a different form of temperature is often seen. It is characterised by being very irregular, usually keeping below 100°. How far this is dependent upon bacterial activity it is difficult to determine; possibly in many cases it is due rather to the absorption of toxic material from degenerated myocardial cells. At all events, salicylate has seldom any beneficial action here even when used without causing symptoms of intolerance, which are so quickly aroused in cases of this type.

In practice I have come to lay stress upon the regularity or "saw-like" feature of the temperature. Where this is absent and the temperature is seldom above 100°, I think severe cardiac cases are little benefited by salicylate, and may easily be harmed by it if nausea or vomiting be induced. But where the temperature is persistently raised at night, even though the evening temperature is quite low, I prefer to continue with salicylate if possible, as I think that under these circumstances there is some smouldering activity of the infection present. My chief reasons for this conclusion are (a) that this type of temperature usually develops from a similar saw-like temperature of higher grade; (b) that relapses of pyrexia are frequent; and (c) that the patient's improvement is seldom satisfactory until this type of temperature ceases.

In some instances rheumatic hyperpyrexia can be reduced by salicylate, but here it is evident that we are dealing with an extremely virulent infection and with usually but little time in which to attempt to control it.

Taken as a whole, therefore, and with due allowance for the difficulties connected with parenchymatous cell changes, the action of salicylate upon the pyrexia of the rheumatic infection is in accordance with the theory that the drug has the power of diminishing the activity of the infection.

Tonsillitis.—Acute rheumatic tonsillitis appears to react well to salicylate treatment. The chronic forms, in which the organisms are buried deeply in the glandular crypts, cannot be expected to be much under the control of any drug circulating in the blood stream. This is of importance, since histological evidence suggests that in human rheumatism there are repeated reinfections of the blood. If these come, as is commonly assumed, from the tonsils, it is evident that an antirheumatic drug, if it could not destroy the organisms at their source, could only do so after they had gained access to the blood stream. This perhaps explains some of the relapses that may occur in patients recently under salicylate treatment or while the drug is being given in small doses.

Other manifestations.—Acute rheumatic nephritis and bursitis, both probably due to local infection, react well in my experience to salicylate. Rheumatic anaemia, on the other hand, is a toxic change and can be only indirectly benefited by the drug. It is noteworthy that this state is not improved by the administration of iron until the activity of the rheumatic infection is at an end. True rheumatic rashes are so irregular in their appearance and disappearance that the effect of salicylate upon them is hard to judge. Erythema nodosum and the so-called peliosis rheumatica I do not regard as truly rheumatic. Rheumatoid arthritis is excluded from the rheumatic group by many authorities, with whom I am inclined to agree.

Other Theories of Salicylate Action.

The "specific" theory of salicylate action in rheumatism which I have supported above is probably widely held, although possibly not always with a just appreciation of exactly what it entails. On the other hand, it is well known that some of those most interested in rheumatic problems are strongly opposed to this view, and it is therefore necessary to examine briefly opposing theories.

Antitoxic theory.—A. E. Garrod[4] has suggested that salicylate possibly possesses the power of neutralising rheumatic toxin rather than of attacking the infecting agent. Thus he writes:—

> Can it be that they [the salicylates] exercise an antitoxic rather than a bactericidal action? It must be granted, as Professor Stockman has pointed out to me, such a conception finds no support in the established facts of pharmacology, and that no parallel example can be quoted of a neutralising effect of a simple chemical compound, administered as a drug, upon bacterial toxins; but neither can any other instance be adduced of such selective influence of a drug upon certain of the manifestations of a disease of bacterial origin.

F. J. Poynton[5] seems to favour a somewhat similar view, more elaborated. Thus:—

> I believe the bacterial poisons are so subtle that they vary with the tissues in which the lesions occur, and I think it probable that salicylates may possibly be specific to some of them and not to others.

In addition to the difficulty already quoted by Garrod, an important argument against the truth of this antitoxic theory lies in the fact that it is diametrically opposed to the evidence afforded by the histo-pathology of rheumatism. As I have attempted to show, it is those symptoms which are dependent upon inflammatory processes that are well controlled by salicylate, while those due to toxic parenchymatous changes are comparatively unbenefited. It would therefore seem that a bactericidal rather than an antitoxic action would best explain the "selective influence" of the drug.

Partial specific theory.—This view, for which I cannot find a more satisfactory name than that given, is widely held. A couple of quotations will demonstrate the theory. A. F. Voelcker[6] writes: "We are not justified in regarding the salicylates as a specific for any and every rheumatic affection." Again, A. Abrams writes: "Salicylates have a specific action only on the articular manifestations."

We must here pause to remind ourselves that the term "specific" may be applied to a remedy in two senses. It may be employed as meaning merely "peculiarly efficacious." Used in this sense, although the above statements become defensible, they are of little theoretical interest since no explanation of the drug's action is attempted. Employed, however, in connexion with a remedy for an infective disease, the term "specific" is usually meant to express that the drug has a bactericidal power of some sort over the infecting agent. Used with this meaning any "partial specific" view becomes full of difficulty. For if the modern view of rheumatism as a definite infection attacking various organs of the body be correct, it is clearly illogical to presume a bactericidal action on the organisms attacking one part of the body and to deny it to those producing similar lesions elsewhere. The only explanation of such a selective action would be that in some organs the foci of inflammation become closed (as in tuberculosis) and thus unapproachable to a circulating drug, and of such a process there is no histological evidence; indeed, the inflammatory foci appear closely connected with dilated vessels.

fails to control such as persist after all signs of such activity have passed. The antirheumatic action of salicylate is seen at its best in rheumatic arthritis because it is here that the symptoms due to inflammatory change are at a maximum, and those due to toxic parenchymatous change at a minimum.

Chorea.—In chorea we have histological evidence of two sets of changes in the central nervous system (*a*) perivascular inflammatory changes from the presence of infecting organisms, and (*b*) toxic changes in the cells of the cerebral cortex. Before discussing the action of salicylate we must consider how far each of these sets of changes is responsible for symptoms in cases of chorea.

In certain acute febrile cases it is clear that we are dealing with an actual infection of the central nervous system. Poynton and Holmes[3] have produced post mortem evidence of this, which has been corroborated by Coombs. It is also confirmed in some non fatal cases by the discovery of streptococci and cells in the cerebro-spinal fluid during the acute stage of the disease. On the other hand, it is probable that many slight cases of chorea are due to a rheumatic cerebral toxæmia rather than a cerebral infection. Of much more importance, however, is the recognition of the fact that the nervous symptoms of chorea may persist long after all rheumatic bacterial activity has ceased either in the brain or elsewhere, being dependent upon the damage already done by the infection to the cerebral cortex. That this is the case is shown by the normal (or subnormal) temperature and the normal cerebro spinal fluid in many cases still showing the nervous symptoms of chorea.

No antirheumatic drug, therefore, can put an end to choreic movements. The most it can do is to diminish the activity of the infection, relieving such symptoms as are directly dependent upon such activity, and thus to limit the supply of toxin which damages the cerebral cells. These latter are then in a position to undergo repair, which when accomplished relieves the nervous symptoms. The fact, then, that salicylate cannot "cure chorea" in no way invalidates the theory that it has the power of diminishing the activity of the rheumatic infection. Indeed, the generally accepted view that salicylate is useful in chorea where signs of active infection (fever, pains, arthritis) are present is in accordance with this theory. When these have ceased salicylate, no matter in what large doses, can do no more to check movements, and at this stage treatment should aim at restoring the structure and function of the cerebral cells by rest, feeding, re education, and such measures.

Carditis.—Here again we find two sets of tissue changes inflammatory changes in the valves, pericardium, and interstitial tissue of the heart muscle, with toxic parenchymatous changes in the myocardium. Of these it is now generally recognised that the latter are productive of most of the ordinary cardiac symptoms, the inflammatory changes producing such symptoms as fever, friction, and possibly certain murmurs. The usefulness of salicylate, however strongly antirheumatic its action may be will therefore be limited in carditis as in chorea. We cannot expect it to relieve the symptoms due to myocardial degeneration any more than we can expect it to remove the signs of mitral stenosis, on the other hand, we must expect evidence of its power to diminish the activity of the infection in the heart and the symptoms dependent upon it.

Such evidence will be forthcoming to anyone who has used salicylate to test this particular point. But very convincing cases are not numerous, because in children most cases of acute carditis show evidence of severe toxic myocardial degeneration, and in adults many are associated with a severe failure of myocardial power. Perhaps the most striking cases are seen in adults who, with a recent history of rheumatic arthritis, show fever, a quickened pulse, and a mitral bruit without much cardiac dilatation. In such cases, which appear to be examples of acute carditis in which the inflammation is acute but the parenchymatous changes slight, salicylate successfully reduces the temperature to normal and puts an end to the infective process. Similar results may sometimes be seen in first attacks of endo or pericarditis in children where there is no considerable dilatation of the heart. Even where the myocardium is severely degenerated the patient's temperature will often react to salicylate treatment if well tolerated, but this will not be associated with any immediate relief to the symptoms of cardiac dilatation.

This inability to cope with the myocardial degeneration and the symptoms thereof constitutes the first limitation to the practical use of salicylate in cardiac rheumatism. But there is a second, again associated with the state of the heart muscle. I have shown elsewhere[1] that the amount of vomiting produced under salicylate treatment depends much more upon the state of the heart than upon the dose of the drug employed. Where the heart is only slightly affected vomiting is only troublesome in 4 per cent of the cases, and now that the proper methods of administration are better understood practically should not occur. On the other hand, where the heart is much affected, particularly where it is severely dilated, troublesome vomiting occurs in about 30 per cent of the cases, and in a large proportion of these is directly attributable to the drug, even though very small doses are employed.

Nodules.—These consist of macroscopic collections of inflammatory products, probably the results of bacterial emboli in end arteries. We cannot tell how long a nodule may be expected to remain, so that we cannot tell if salicylate directly hastens their absorption. In investigating the theory of salicylate action the matter of rheumatic nodules does not assist us. All that one can say is that if salicylate can put an end to rheumatic activity it is probably doing all that is possible to hasten the disappearance of nodules. I have elsewhere[1] discussed nodule formation as a rheumatic relapse under salicylate treatment.

Pyrexia.—As in other infections the temperature in rheumatism is a most important index to the activity of the infection. The fall in the temperature in the rheumatic arthritis of adults, coinciding as it does with marked local and general improvement, gives the strongest support to the specific claim of salicylate.

On the other hand, there is often seen, particularly in cases of cardiac rheumatism, a "saw like" temperature with about 2° difference between the morning and evening readings, the latter reaching 101°–2° F. This is sometimes referred to as the fever of the "rheumatic state" but it denotes, I am convinced, some activity on the part of the infection. It is often stated that salicylate does not control this type of rheumatic pyrexia, but in my experience it is usually satisfactorily modified by which the suction force can be varied from an equivalent of 5 to 100 lb. air pressure.

The vascularity of the larynx is favourable to the process of dry cupping, as the vessels enter and pass out at definite sites. There are two chief and two subsidiary sources of arterial supply, and the veins and lymphatics accompany the arteries almost exclusively. The box of the larynx, chiefly made up of the two wings of the thyroid cartilage, has no vessels perforating its immediate sides, but they pass into it above and below. Above the superior laryngeal arteries pierce symmetrically the thyro-hyoid membranes, being branches of the superior thyroid arteries. Having entered the interior of the larynx they spread out like the roots of a plant in the submucous tissue of the inner laryngeal lining. These branches are mostly directed to the posterior aspect, and in the lower half of the area of the thyroid cartilage meet similar ramifying branches coursing up from below—viz., those of the inferior laryngeal artery, which has similarly pierced a membrane, the crico-thyroid. The inferior laryngeal artery is a branch of the inferior thyroid and also has its intralaryngeal branches directed to the posterior part of the lining of the larynx. While the superior laryngeal veins follow closely the same artery, the inferior laryngeal veins chiefly join the more centrally situated inferior thyroid veins. The subsidiary vessels are the crico-thyroid arteries, one on each side, which spread inwards from the superior thyroid arteries as they pass down to the thyroid body. These two small vessels run in horizontally from each side on the crico-thyroid membrane and meet and anastomose in the middle line. Branches pass from them through this membrane and spread out freely in the lining of the anterior aspect of the larynx. There is in this manner a special blood supply given to the anterior part of the lower region of the larynx which compensates for the large distribution of vessels at the posterior part, to which the superior and inferior laryngeal arteries are mainly directed. The lymphatic vessels similarly pass through the membranes above and below the thyroid cartilage, following the blood-vessels more or less closely. Those accompanying the superior artery go into the superior deep cervical lymphatic groups of glands, while those with the inferior pass to the inferior deep cervical glands. There are other lymphatic vessels which pierce the crico-thyroid membranes directly and join small lymphatic glands lying on the surface of this membrane. No vessels, either arterial, venous, or lymphatic, pierce the wings of the thyroid cartilage.

The anatomical arrangement of these arterial, venous, and lymphatic vessels has an important bearing on the application of dry cupping. It indicates that for the most effective relief of vascular and œdematous congestion of the interior of the larynx the cups must be correctly placed anatomically to get the maximum result. The cups should therefore be applied over the posterior half of the thyro-hyoid membrane and over the crico-thyroid membrane both laterally and in front. In this way there can be brought about a lessening of intralaryngeal congestion both by retarding the entrance of blood and by facilitating venous and lymphatic circulation onwards and so relieving venous and lymphatic engorgement.

I append brief notes of four cases.

CASE 1.—The patient, a man of [illegible] the age, was sent to [illegible] complaining of difficulty [illegible] breathing [illegible] marked inspiratory dyspnœa, especially on lying down and on exertion. On inspecting the larynx the vocal cords and their movements were found to be normal, but a subglottic swelling was seen on the left side bulging into the air-passage. There was some tenderness on pressure over the left thyroid cartilage and a fulness filling up the hollow in the lower part of the inferior carotid triangle. He was taken into the hospital at once, as some of the dyspnœa attacks had been so severe that there seemed a likelihood of tracheotomy being required. Dry cupping was used, the cups being placed on the left side over the thyro-hyoid membrane, on the front of the larynx over the crico-thyroid membrane, and lower down over the position of the lateral swelling and at the position of the entrance of the inferior laryngeal artery into the larynx. After the first application he expressed himself as feeling more comfortable, saying that he was breathing more easily and that the sense of suffocation had diminished. He was in the hospital some weeks and learnt to apply the cups exactly and to use the apparatus regularly night and morning for himself. The subglottic swelling became much less prominent, and this seemed to be a result of the cupping. It was subsequently found that Wassermann's reaction was positive and he was put on potassium iodide, when he still further improved.

CASE 2.—The patient, a man aged 22 years, suffering from well-marked laryngeal tuberculosis, came to the hospital complaining of difficulty of breathing and swallowing and of pain in the throat. The epiglottis and vocal cords were seen to be swollen and ulcerated, and the arytenoid apices infiltrated, red, and inflamed. Dry cupping was made use of over the crico-thyroid and the thyro-hyoid membranes on both sides and at the lower and lateral parts of the larynx. The pain was much relieved, and he swallowed a glass of milk with greater ease than he had done for a very long time. The dry cupping is being applied every morning at the hospital, where he is now under treatment.

CASE 3.—A man, aged 32 years, who worked in a dusty warehouse, had contracted a head cold followed by partial loss of voice and marked hoarseness. On inspection the interior of the larynx was seen to be very congested and somewhat swollen over the ventricular bands, the vocal cords being red. Dry cupping was applied over the usual positions with marked improvement of the hoarseness, and the vascularity of the larynx could be seen to be distinctly lessened. After two more applications the voice became normal.

CASE 4.—A young woman, a private patient, was sent on account of loss of voice and pain deep in the throat (larynx). The vocal cords were seen to be much suffused, but approximated well on phonation. Dry cupping having been applied over three positions on each side, the pain ceased and her voice returned. I think that this was a case of catarrhal laryngitis, but there may have been an element of functional aphonia.

When first commencing the treatment it is well to apply it for a minute only at the longest until one observes the effect on the skin, as some patients, having very susceptible skins, are liable to get ecchymosis. Others, as in the case of these just cited, can bear the cups on the skin for quite five minutes without any visible mark being produced and even a reapplication without the skin becoming very deeply reddened at the site of suction. I have now used the cupping method in a considerable number of cases with good result. This treatment might even be useful in such cases as laryngismus stridulus (laryngeal asthma) in young children where there is a spasm of the muscles of the larynx and vascular engorgement. The mucous membrane of the larynx is thin and closely adherent on the true vocal cords but more vascular, thicker, and loosely adherent over the other parts. It therefore quickly becomes congested, swollen, and even œdematous as in acute laryngitis. Dry cupping might be advantageously employed, but I have not yet had an opportunity of trying it under such conditions.

Harley-street, W.

The only possible alternatives to the specific view would appear to be either the "antitoxic theory" already considered or the "non specific theory" to be discussed immediately Poynton, who admits the difficulty, is drawn to both alternatives, but apparently is not well satisfied with either To quote the passage in full[5] —

> I do not dispute that some rheumatic lesions, notably arthritic and muscular pains, are greatly relieved and the temperature is lowered by these drugs, but further than that I am not prepared to go How can such a position as mine be justifiable? I believe the bacterial poisons are so subtle that they vary with the tissues in which the lesions occur, and I think it probable that the salicylates may possibly be specific to some of these poisons and not to others I am even tempted to feel that their specific action upon rheumatic arthritis is perhaps overrated, for I have seen other acute forms of arthritis relieved by them It does not follow, I think, because acute rheumatic arthritis subsides rapidly that it is the salicylates which produce this subsidence though they may relieve the pain

Non specific theory—It might be logically held that salicylate has no power to control the activity of the rheumatic organism wherever displayed Some are drawn to this view, although nowhere can I find it very definitely put forward How far Poynton is prepared to go in this direction has already been shown L G Guthrie[6] may also be quoted —

> Salicylates relieve pain and lower temperature I do not think they cure rheumatism and am sure they do not avert cardiac affection Drugs may palliate but do not cure either rheumatism or chorea

Before such a view can be accepted some explanation of the reaction of rheumatic arthritis to salicylate must be forthcoming, particularly in connexion with the fall of temperature, which, when accompanied by local and general improvement, is usually accepted as strong evidence of a lessening activity on the part of an infection. The only alternative to allowing a specific action to salicylate here would seem to be to deny that the drug acts any more successfully upon rheumatic than on any other form of infective arthritis And this would be against general experience, for, although every one has seen some lowering of the temperature under salicylate in other infective conditions, yet it is generally acknowledged that as regards its degree, constancy, and permanence the fall of temperature in rheumatic arthritis under the drug is peculiar

Chemical Support of Specific Theory

Space will not permit me to do more than refer to Stockman's important article on the Action of Salicylates in Rheumatic Affections,[9] in which he shows that the antirheumatic power of salicylate and chemically allied drugs depends upon the relative positions of the carboxyl and hydroxyl groups He writes —

> The action of salicylic acid in acute rheumatism is undoubtedly specific It is of little or no therapeutical value in other febrile diseases and it exerts no action on the healthy man from which one could infer its action in rheumatic fever But besides clinical evidence the chemical evidence points conclusively in the same direction

Conclusion

That salicylate has the power of diminishing the activity of the rheumatic infecting agent may be taken as the working basis of salicylate therapy in rheumatism, and the drug should be administered with the sole view of controlling the bacterial activity Of this the temperature chart is as accurate an index in rheumatic as in other infections (e g, tuberculosis) Care must be taken to discriminate between symptoms directly due to active rheumatic inflammatory processes and those dependent upon toxic parenchymatous changes which may remain long after all bacterial activity is at an end

Note on dosage.—The temperature chart is the guide to the dose of salicylate to be employed. Used solely with a view to controlling bacterial activity, the effective range of dosage for child or adult is usually from 60 to 120 grains per diem. Less than 1 drachm daily is rarely sufficient, more than 2 drachms need seldom be given. Much larger doses than these have been shown to be safe if properly administered, and if necessary to gain control may be used, but for the most part "massive doses have been administered in cases of chorea in which there was no evidence of bacterial activity remaining

Any dose greater than 100 grains daily should be given, as Dr D B Lees teaches, subdivided into 10 doses in the 24 hours Large infrequent doses should never be given, particularly in children Constipation must be avoided The sodium salicylate should be combined with an equal dose of sodium bicarbonate, I have not found the double quantity of soda necessary in doses of this grade. Vomiting in cases of severe cardiac dilatation may be difficult or impossible to prevent, but in other cases may be avoided for the most part The more serious symptoms of salicylate poisoning (acid intoxication) should nowadays never be allowed to arise

DRY CUPPING IN LARYNGEAL AFFECTIONS

BY W STUART LOW, F R C S ENG,
SURGEON TO THE CENTRAL LONDON THROAT NOSE AND EAR HOSPITAL.

FOR some time I have been using dry cupping of the external surface of the larynx and adjacent area of the neck with very beneficial effect in some laryngeal affections, but I can find no record in laryngeal literature of its employment for this class of disease That dry cupping should not have been used for the relief and amelioration of laryngeal trouble is the more remarkable since it is so readily and so easily applied, and the anatomy of the parts, particularly the blood supply, lends itself advantageously to such treatment

The best and most easily worked apparatus for regular and systematic dry cupping is a suction apparatus (tankless), an American instrument, the agents for which in this country are Messrs Rouse, of Wigmore street There are two sizes of this machine, the No 20, with three cylinders suitable for consulting room work, and the smaller portable one, which I have found quite sufficient and most useful at the bedside I have had cups made of various sizes and shapes for adaptation to the front and sides of the larynx, and have found it best to have the edges of the cups covered with rubber so that any inconvenience the patient might feel when the suction is strongest may be minimised Some of these cups are half moon shaped, others horse shoe shaped Suction can be applied effectively to one or both sides of the larynx simultaneously There is an adjusting mechanism on the instrument by wire leads to an electrode connected to the patient On starting the machine and separating the discharging rods the patient is subjected to powerful oscillatory discharges from the jars I use this current chiefly for the treatment of another form of stasis about which we hear much—intestinal stasis With one jar attached to a rectal electrode and the other to an abdominal a powerful current passes between the two, and that it causes contraction of the unstriated muscle of the intestine is shown, I think, in the resultant relief of the constipation which is often obtained Not all cases of intestinal stasis can be relieved in this way I have, however, cured one case of 25 years standing with colitis of five years standing Until she had this treatment the patient had had no normal evacuation of the bowels for 25 years Other cases have done well Failures, however, occur In one subsequently operated on by Sir Arbuthnot Lane the patient told me that the large bowel, which was removed *in toto*, was in a very diseased condition and quite incapable of recovery When I saw him last he was feeling quite well and was about to proceed to the front

Another use of the static induced current is to stimulate muscles which have degenerated from one cause or another, as in cases of anterior poliomyelitis I believe it is more efficient for the purpose than faradic or sinusoidal. The mechanical effects of static electricity are obtained even when the current is broken up, if I may so describe it—that is, when the electricity instead of travelling in a massive spark is broken up into a spray as in the static brush discharge, or is broken up in another way as in vacuum tubes, glass tubes that is, in which there is a partial vacuum The static brush discharge is used for treatment of stasis in parts which are too sensitive either from inflammation or locality to permit of the use of the wave current A gouty toe, for instance, is sprayed for half an hour with manifest relief resulting to the patient In treating a varicose ulcer the effects can be watched At first as the current is applied some blanching of the skin takes place This must be due to a preliminary contraction of the arterioles due to stimulation of their muscular coats Soon relaxation follows, and a more permanent reddening of the skin results As we watch the ulcer we see an exudation of plastic lymph appearing on the base, and after half an hour's treatment I usually derive the impression that the ulcer is smaller and more shallow However that may be, the patient will usually tell you next day that the pain is better, and after a shorter or longer series of treatments healing takes place This current is most useful in the treatment of chilblains, acne and I once used it with gratifying success in a case where a hypertrophied scaly condition of the skin followed on a prolonged irradiation with radium The discharge breaks up the air into ozone and nitrous oxide both of which are antiseptics

The vacuum tube discharges are used when we wish to obtain an effect stronger on the one hand than the static brush discharge effects and weaker than the static wave current They are particularly useful in searching for tender points in a case of neuritis These if not too deep are quickly [illegible] by this means In the treatment of neuralgia of the supra orbital or infra orbital nerves the vacuum tube is very useful as also in the treatment of acne herpes zoster and other skin conditions Specially shaped vacuum tubes are used in the cavities of the body, some for rectal use for fissures and inflamed piles, others for vaginal, urethral, and so on

I mentioned at the beginning of this paper that there were other therapeutic effects of the static currents which I could not explain as being due to mechanical causes only First there is the sensation of well being derived from treatment by the static wave current by a certain number of patients, but not by all This is quite well marked, and a patient who feels these effects will probably refer to it without being asked Patients certainly retain a part of the charge after treatment ceases, as is shown by the fact that one can sometimes get a spark out of them, and I suppose this extra charge suits some people In addition, there is an increase of the urea output in the urine, so that I suppose metabolism is increased There is also the deep massage effect above referred to More important effects are those derived from the static bath In this the patient is seated in a chair on the insulated platform, which is connected to the negative part of the machine, the positive being grounded, the spark gap is opened wide and the machine run slowly The patient has no sensation except of a gentle breeze or of the hair standing on end From 20 minutes to half an hour of this treatment is most soothing to the nervous system, leads to quiet sleep in those suffering from insomnia, and is generally useful in quieting down people who have been worked up by worries and anxieties or who are suffering from nervous irritation due to other causes I use it, for instance on patients who have complained of sleeplessness or too much exaltation following on treatment with the static wave current Lastly, the most useful application of the static brush discharge is its application in cases of neurasthenia People who are depressed, cannot sleep, suffer from dyspepsia, are anxious, easily tired, worried by business, &c, are they to whom this treatment is applied

The brush discharge is applied up and down the spine for 20 minutes to half an hour daily for two weeks In the second week an amelioration of the symptoms begins, and then the treatment is intermitted given three times a week, then twice, and finally stopped Sometimes it works like a charm I remember a lady who had a headache daily and a severe headache which necessitated retirement to bed every two weeks She began treatment, I recall, just before Derby day, and had a violent headache after seeing the Derby at which a suffragette was killed She had the course of treatment above outlined, but somewhat interrupted by social duties I saw her in the following October, and in the whole of that interim she had had no headache that a dose of acetyl salicylic acid would not arrest, and very few of them

I conclude then that we have in the various applications of static electricity methods of treating a variety of conditions medical and surgical, not all of which do well under the ordinary methods of treatment in vogue

LITERARY INTELLIGENCE—The Cambridge University Press announce for early publication the third edition of Shipley and Macbride's "Zoology," which has been thoroughly revised and in parts rewritten The newer discoveries in the laws of inheritance are dealt with in the introduction and there are many new illustrations

SOME USES OF STATIC ELECTRICITY IN MEDICINE AND SURGERY[1]

By JOHN J GRACE, F R C S Eng,
CHIEF ASSISTANT IN THE X RAY DEPARTMENT, ST BARTHOLOMEW'S HOSPITAL.

THE effects of static electricity may be summarised as being chiefly but not entirely mechanical, just as those of the constant current are chiefly due to the carriage of ions by the current, and those of high frequency are chiefly due to its heating effects Static electricity may be converted into high frequency or into X rays, but in either event it loses its static quality in whole or in part I do not think any effects due to the carriage of ions can ever be obtained from static electricity Other therapeutic effects are ascribed to static electricity such as its suggestion effects There are therapeutic effects of static electricity other than mechanical, to which I will refer more particularly later I do not know what they are due to precisely, but I am sure they are not due to suggestion

I will deal first with the mechanical effects and will begin with the static wave current, the most generally useful current there is An electrode is applied to the bare skin of the patient, who is seated on an insulated platform Special electrodes are applied to special parts This electrode is attached by a wire to the positive pole of the machine, the negative pole is grounded, and the machine is started The spark gap is then opened If the machine is properly regulated a spark travels across the gap at the rate of 120–200 a minute In the intervals of the spark the patient is filled like a Leyden jar with static electricity When the spark crosses over the gap he is discharged at one point, the part with which the electrode is in contact The effect of this sudden discharge at one point or in one small area is a violent commotion of all the tissues in the neighbourhood of that point It is, in fact, a deep massage of all the tissues but intensifying towards the electrode Theoretically we should expect such a commotion of the tissues to relieve stasis Practically we can see it do so If we take a case of simple chronic synovitis of the knee joint we have an ideal condition in which to study results In such a case, often in one treatment, usually in three or four, an obvious and marked reduction of the swelling takes place So impressed am I with the results obtained in these cases that if I did not see and the patient did not feel a marked improvement after three or four treatments I should suspect that the diagnosis was wrong and that I was dealing with a tuberculous joint Having said and seen that the effect of this treatment is to relieve stasis we have but to ask ourselves, In what pathological states have we stasis? to arrive at a conclusion as to the kind of case in which static electricity is useful

I do not wish to enter into the pathology of lumbago, sciatica, or brachial neuritis I am not qualified to do so if I did wish it, but any of you who have been plagued with these troubles know that there is something in the muscles or nerves which ought to be eliminated This treatment I know from experience in my own case and that of many others will eliminate it

An enlarged prostate can be reduced and the symptoms due to it relieved Here are the notes of a typical case The patient, aged 57, had had symptoms of enlarged prostate for five or six years, he rose three or four times a night to urinate There was a very small amount of residual urine Per rectum the prostate was found to be moderately enlarged, its consistence somewhat firmer than normal The static wave current is used with a metal rectal electrode which has a concavity which rests against the posterior aspect of the prostate The part of the electrode opposite the sphincter is insulated. Treatment was given for 20 minutes daily After eight treatments I have the following note Patient retired to bed at 10 30 P M Got up and emptied bladder at 2 A M Awakened from habit and not by his bladder Did not wake again until 8, when he got up After 16 treatments he arose once only at 5 A.M He remarked that his stream was less crooked and stronger Some of these patients progress to complete alleviation of symptoms, others have to rise once at night instead of four or five times In a majority of cases there is some improvement

A subinvoluted uterus can be contracted. Dysmenorrhœa is often relieved I have reduced enlarged livers and enlarged thyroid An enlarged spleen can be reduced In rheumatoid arthritis of the knee I have had considerable success, in that of the hip joint I am sorry to say no success There is in fact a wide variety of chronic conditions and a few acute ones such as sprains where the static wave current gives good hope of prompt relief

If, as I believe to be the case, the static wave current relieves stasis by the commotion set up by the interruption of the current, how much greater and therefore more effective must be the commotion set up by the static spark Here the whole charge resident in the body of the patient rushes to an exit at one small point, the point of exit of the spark That sparks are most efficient is seen in cases where such indurations as synovial thickenings get softer and less marked from day to day Unfortunately I must add, however, that I have had no success with them or with anything else in the treatment of the most obvious indurations of all—i.e, those around the knuckles in rheumatoid arthritis of these joints I believe that failure here may be due to the fact that these joints are too tender to allow of the application of a really effective spark to them.

Another effect, and a very important one, of the static spark is the relief of spasm in muscles connected with inflamed nerves and joints Sometimes these muscles can be felt to be in a state of spasm, at others the inability to make certain movements discloses it For instance, I had a patient recently under treatment who could not use his deltoid at all This was after a fall from a bicycle, when he fell on his hand and doubtless bruised the muscles around the shoulder joint After a few sparks applied to the deltoid region he immediately had much more use of the muscles which raise the arm to a right angle Next day it was as useless as ever and again immediately responded to the sparks, and so again the next day After the third day the improvement continued. It seems to me that only spasm could account for such immediate recovery and loss of power again next day

The following is the arrangement of the static induced current Two Leyden jars are connected by their inner coatings to the two poles of the static machine From each of the outer coatings a the right lung, and on the left side (three lobes) pleurisy and early broncho pneumonia

---

[1] A paper read before the Hampstead Medical Society

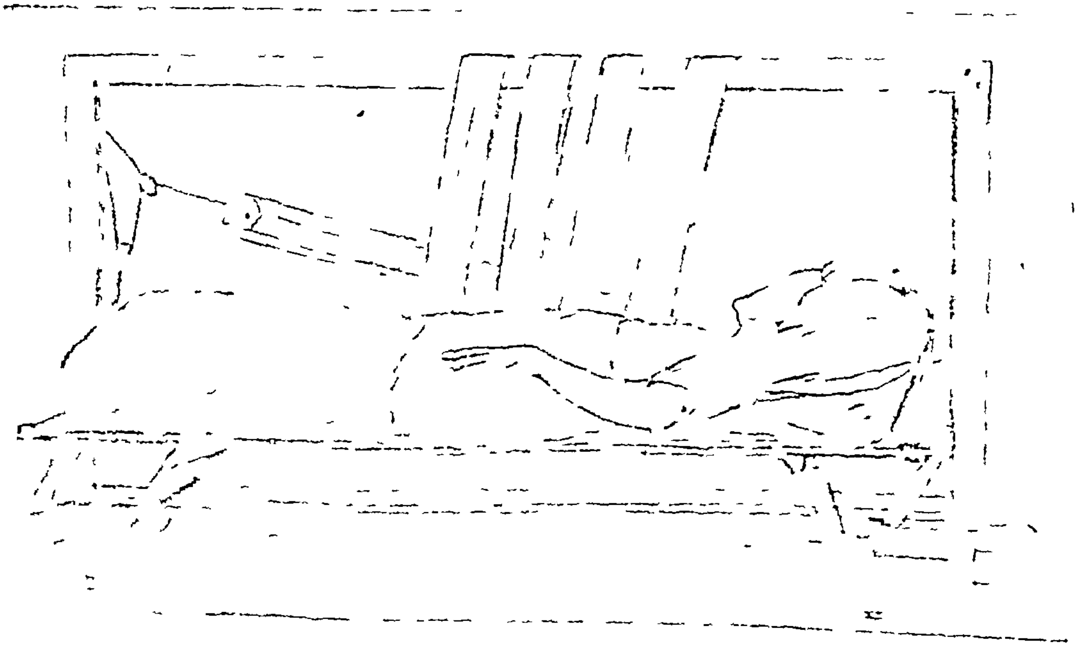
This case seems to show a remarkable accident The pointed broken handle of a pitchfork pierced this man's scrotum, it was deflected by the pubic bone into the anterior abdominal wall and so on into the chest wall He must have doubled himself up when the point was in the abdominal wall, thus causing it to pass anterior to the ribs, through the pectoralis major origin, and finally to stop at and break the second rib, where it deposited the cloth and hay At the inquest evidence showed that a fellow workman pulled some 2 feet of handle out of the man's body The patient then "walked" three miles home and drove ten miles to the hospital Presumably the correct treatment would have been to lay open the whole track, but there was no evidence until the formation of the abscesess that the fork handle had made any further injury than that in the scrotum

A SIMPLE SPLINT FOR FRACTURES OF THE UPPER EXTREMITY

By M W B OLIVER, M.A, M.B, B C CANTAB, F R C S ENG,

LIEUTENANT ROYAL ARMY MEDICAL CORPS

THIS splint has been devised for the treatment of compound fractures of the upper extremity, and it is especially useful in cases where there is an extensive wound requiring much dressing It is also extremely useful in cases of simple wounds in which there is no fracture The splint consists of a horizontal wooden bar supported by an upright at each extremity of the bed The arm is suspended from the horizontal bar by means of flannel slings In place of these a gutter splint of perforated zinc suspended by cords may be used As a rule the flannel slings are more convenient and facilitate the dressing of the wound If a fracture is present extension may be applied as shown in the accompanying diagram



Illustrating the splint for fractures of the upper extremity

The advantages of the splint are 1 It is very simple and can easily be made by any carpenter 2 The patient is made very much more comfortable, as with the arm sling he is able to move his body without interfering with the position of the arm 3 Extension can be applied very easily 4 The dressing of the wound is very much simplified and is less painful This splint is a modification of the "Balkan" splint, which was devised for the treatment of fractures of the lower extremity, and has been used in this hospital with very satisfactory results

THE REMOVAL OF A SEBACEOUS CYST UNDER SUGGESTED ANÆSTHESIA

By J W ASTLEY COOPER, L R C P & S EDIN, L F P S GLASG,

RESIDENT PHYSICIAN AT GHYLLWOODS SANATORIUM, CUMBERLAND

THE patient had at the time of operation been under treatment for chronic alcoholism by hypnotic suggestion for six weeks Incidentally complaining of a sebaceous cyst of some years' standing in the skin of the chest over the sternum which was slowly getting larger, I proposed its removal during one of his hypnotic sittings This was agreed to I hypnotised the patient and suggested total absence of pain during and following the operation I then dissected out the cyst (about as big as a large filbert) The wall was strongly adherent, and had to be torn away piecemeal at one spot, to ensure its destruction I subsequently swabbed out the cavity with tinctura iodi The patient gave no indication whatever of any feeling of pain or discomfort, either during this small but painful operation or during the subsequent healing of the wound but on being roused expressed surprise that all was finished and that no pain had been felt

[illegible]

CONGENITAL LYMPHANGIOMA SITUATED OVER THE STERNUM

BY JOHN A C MACEWEN, M B , C M , B SC GLASG ,
F R F P S GLASG ,
SURGEON TO THE ELDER HOSPITAL ASSISTANT SURGEON GLASGOW
ROYAL INFIRMARY SENIOR ASSISTANT TO THE REGIUS
PROFESSOR OF SURGERY UNIVERSITY OF GLASGOW

IN THE LANCET of July 19th, 1913, a case of large dermoid cyst occurring over the sternum was reported by me, and the one now to be described resembled it in situation and in being congenital and cystic, but the patient was younger and the appearance of the tumour very different

The patient, a girl aged 8, was admitted to the Elder Hospital in September, 1913 Her mother stated that she had a birthmark of about the size of a bean, which had always been white and soft until recently, and which was situated over the sternum A few weeks *prior to admission* the tumour first became hard and of a blue colour, and then rapidly enlarged, becoming red and inflamed as it did so On admission a large cystic tumour was seen, situated in the middle line, over the sternum, commencing about 3 inches below the episternal notch, and extending downwards a distance of 3½ inches The tumour was pear shaped, with the stem directed downwards and inclined to the right side, its greatest breadth was 2½ inches, and it projected fully an inch from the surface That it was cystic was apparent on superficial examination, and tense *fluctuation* was *marked* On *close inspection* the skin over the tumour, which showed no evidence of inflammation, was found to be thin and stretched, and it was seen to contain small superficial bluish pearl like cysts in places The condition was painless and did not *occasion* any marked discomfort

An operation was performed on Sept 24th An oval incision was first made so as to remove the area of affected skin On carefully deepening the incision a sac wall was seen, which was thin, pearly, and translucent, and which contained fluid, the appearance strikingly resembling that of the tunica vaginalis *testis* when *exposed in the operation* for hydrocele An attempt was made to remove this sac entire, but it was firmly adherent to the subjacent tissues, and, unfortunately, ruptured when almost freed, several ounces of clear amber fluid escaping The tumour extended down close to but did not involve the sternum The wound was stitched up, and the child made an uneventful recovery

On examination of the tumour it was found that while the largest cyst had been ruptured, there were a few much smaller ones also present, in addition to those in the skin itself, which have already been referred to

Dr J Anderson, pathologist to the Victoria Infirmary, Glasgow, very kindly made sections from various parts of the tumour, *and reports* as follows —

The epidermis is very variable in thickness and in outline, small papillary projections appearing at places The horny layer is scanty, and the Malpighian varies as to thickness and interpapillary processes In one section a small cyst is seen in the epidermis resembling an eruption cyst, which presents an endothelial lining and thin fibrous wall and is supported by cells of the Malpighian layer to the inner and of squamous to the outer aspect The contents are mucinous and present several lymphocytes The true skin is atrophied as a whole although apparently increased as compared with the Malpighian layer, and the apparent increase is added to by the presence of inflammatory proliferation of connective tissue and a few lymphocytes There is a *scarcity of* glands generally, and particularly of sebaceous glands Small mucinous areas, cyst-like in character, are seen in the deeper layers of the corium, often surrounded by inflammatory foci, and slightly larger cysts of the same character are found in the fatty tissues Some of these cysts present marked hæmorrhages from their walls into the *interior* The fatty tissue is, as a whole, well represented, and at places there are hæmorrhages into it, and also inflammatory *infiltrations of the stroma The margin of the large cyst* presents a well defined wall composed chiefly of fibrous tissue, but containing a little unstriped muscle fibre, and is richly vascular, the *vessels* in places being engorged It is lined by flattened endothelium I consider the condition as one of lymphangioma.

Glasgow

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

AN EXTRAORDINARY ACCIDENT

BY T O THOMPSON, M B , B CH OXON ,
LIEUTENANT R.A.M C FORMERLY CASUALTY HOUSE SURGEON
RADCLIFFE INFIRMARY OXFORD

THE patient, a man aged 34, was admitted into the Radcliffe Infirmary, Oxford, on Jan 28th, 1914 He had fallen 7 feet off a haystack on to a pointed handle of a hayfork, which produced a wound 3 inches long in his scrotum This *did not* appear to extend beyond the skin and dartos muscle He complained of pain in the right side, but no lesion or any bruising could be found on the right side or the arm Two days later the pain was less severe, *fomentations* having been applied On the next day pain at the right nipple was *felt on coughing*, and breathing friction rub was heard The breath sounds were not affected, and *there was no obvious* dulness on percussion

Three days later the patient developed a fluctuating area under the right pectoral, which on evacuation contained purulent blood effusion and two pieces *of straw* 3 inches and 6 inches long This area was drained freely and the patient improved Two days later another subcutaneous abscess formed mid way between *the right* nipple and the right side of the scrotum This was opened and drained, and proved to be a long purulent track Later a piece of hay was removed from each *abscess* cavity The patient continued to become worse, the *temperature rising and* the respirations becoming more rapid An extensive œdema of the anterior chest wall occurred with an inflamed area internal to the right nipple This was freely incised but no pus was found The patient developed broncho pneumonia and died

A post mortem examination showed a *complete* subcutaneous track from the wound in the right *side of the* scrotum to the infraclavicular region, with putrefaction along the whole track, and under the pectoralis major a cavity in the same condition in which were *found* wedged in one corner a piece of tweed cloth from the man's trousers and some straw and hay There was inflammation of the right side of the neck and lower *face and the* whole anterior chest wall The second rib was fractured and *osteomyelitis* was present The spleen was almost fluid while the heart was flabby *There* was pleurisy, with solid œdema of the lower lobe of was obvious bulging of the sternum due to enlarged thymus Dr. Williams here discussed the clinical signs of hypertrophy of thymus. He referred to a complete description by Oelnitz,[1] who divides cases into four groups (1) those with sudden death, (2) latent forms, with sudden symptoms calling for immediate intervention, (3) silent forms, with intermittent and transitory respiratory symptoms, and (4) forms with continuous manifestations with intermittent symptoms. The symptoms are (1) dyspnœa, generally with cyanosis, (2) often stridor, (3) epistaxis, (4) malnutrition and cachexia. Physical signs are (1) œdema of eyelids, (2) exophthalmos, (3) increased tension of fontanelles, (4) persistent facial cyanosis, (5) superficial cervical veins dilated, (6) inspiratory contraction of platysma, (7) asymmetrical arching of sterno-costal articulation, more frequent on right side, (8) enlarged thymus can often be felt beneath the sternum, (9) abnormal percussion dulness in thymic region, (10) auscultatory vascular souffle with head over-extended, and (11) radiographic shadow above cardiac shadow Dr Williams quoted Sajous to show that the function of the thymus is to supply through its lymphocytes the excess of organically combined phosphorus or nucleins required, especially by osseous and nervous systems during growth This theory, besides explaining thymic idiocy, thymic marasmus, and thymic dwarfism and rhachitis, explains thymic Graves's disease through the toxæmia induced by excess of nucleins or nucleic acid In 133 cases of Graves's disease which came to necropsy after operation Mathis found abnormally large thymus in 78 5 per cent —Dr Feiling showed 1 A man, aged 30 years, with very large hands the feet being normal, teeth regular, and the head flattened and elongated in the antero-posterior diameter A skiagram showed the pituitary fossa slightly enlarged There was loss of sensation in the forearms, and heat and cold sensation was lost, much wasting of interossei and thenar muscles, extensor plantar reflexes, and greatly increased knee-jerks Diagnosis syringomyelia. 2 A man, aged 36 years, suffering from Myopathy of the Facio-scapulo-humeral Form, first noticed 11 years ago The peculiarity in the case was that although there was a family history it was confined to a paternal grandfather

Reviews and Notices of Books.

A Text book of Pathology for Students of Medicine

By J GEORGE ADAMI M.A. M D F R S, Strathcona Professor of Pathology McGill University, and JOHN McCRAE M D M R.C P Lond, Lecturer in Pathology and Clinical Medicine, McGill University, Montreal. Second edition revised and enlarged. Illustrated with 395 engravings and 13 coloured plates London Macmillan and Co, Limited. 1914 Pp 878 Price 25s net

THE authors, we think, are amply justified in their contention that the fact that this text book "has measurably succeeded in its purpose is inferrible from the early exhaustion of the large first edition which appeared in 1912 and was reviewed in THE LANCET of Feb 1st, 1913

The number of pages has been increased from 759 to 878 while 91 engravings and two coloured plates have been added, making the total number of excellently clear engravings 395 and that of coloured plates 13 It seems to us that the whiteness of the paper is more marked, and consequently the printed matter stands out more sharply than in the first edition Amongst the changes—all improvements—we notice the relegation of the chapter upon monstrosities and abnormalities to an appendix and a simplification of the classification of tumours A new chapter on the more important infections and their prominent features has been added A very useful addition is the syllabus placed at the beginning of each chapter detailing its contents with page references The volume is completely cross indexed. Taking the work as a whole, it is evident that while the facts of pathology have not been neglected, continued emphasis has been placed upon the reasons underlying pathological conditions

Part I has been very considerably augmented and improved, and certain rearrangements and additions made The chapter on regressive tissue changes precedes that on progressive tissue changes In connexion with the subject of immunity and its "stupendous" literature, we think the authors have exercised a wise discretion in giving a workable plan by which immunity can be understood, based largely upon Ehrlich's views The additions under the head of surgical shock —not forgetting the contributions of Crile—are valuable and practical. As regards the regeneration of bone, we note that the authors are not as yet prepared to accept the views of Macewen ("The Growth of Bone," reviewed in THE LANCET of March 30th 1912) and others, who deny that the periosteum plays any part in the regeneration or even in the growth of bone The results of the cultivation of tissues, known as "growth *in vitro*" find a place Chapter IV (pp 186–258), on the more important infections and their outstanding features, successfully attempts to marshal under one head information on an important subject that in the previous edition was widely scattered. The scope of the new chapter will readily be grasped when we cite the subjects with which it deals—viz, diseases due to lower bacteria, bacilli, higher bacteria, filterable viruses higher fungi, and protozoa, not omitting the group of diseases classed as spirochætoses

Part II deals with special and systemic pathology and occupies about half of the text It must be difficult even for teachers of experience to decide what to include and what to omit Marked additions and improvements have been made in all the chapters Perhaps more illustrations would add value to the chapter on the nervous system As it stands it is none too long There are several welcome illustrative reproductions of specimens from McGill Pathological Museum The short but practical account of the bones is well worth perusal and careful study

The authors we think have succeeded in producing a highly attractive volume, at once practical, philosophic and suggestive Further, we are of opinion that they have classified the facts and so correlated them that the reflective student not only will be stimulated to add by his own endeavours to the progress of pathology, but also will find that the acquisition of the facts themselves is rendered easier by the plain, straightforward consecutive and logical manner in which the authors have presented them The "get up" apart from the subject matter, is excellent

What is Adaptation?

By R E LLOYD M B D Sc Lond Professor of Biology Medical College Calcutta. London Longmans Green and Co 1914 Pp 110 Price 2s 6d net

IN the preface to this book we are told that it is "not scientific in the usual sense, being influenced considerably by M Bergson's philosophy," and we learn further from the book itself that the author's biological creed is ultra mutationist As an ardent anti selectionist Dr Lloyd questions, perhaps correctly the intellectual honesty of those Mendelians who profess a lingering belief in natural selection as an instrument of organic

Medical Societies.

SOCIETY OF MEDICAL OFFICERS OF HEALTH

Criminal Abortion and Abortifacients

A MEETING of this society was held on Jan 8th, Mr **HERBERT JONES** the President, being in the chair

Dr **W F J WHITLEY** read a paper on Criminal Abortion and Abortifacients He said that criminal abortion was produced or attempted in one of three ways—namely, by means of violent purgation, by the ingestion of drugs having a real or supposed poisonous action upon the fœtus itself or on uterine muscle, and by mechanical interference The abortion which was unsuccessfully attempted was perhaps more serious and far-reaching in its consequences than that which accomplished its object for in the latter life was utterly destroyed and in the former it was maimed and disfigured at its very inception, and the infant when born was frequently puny, undeveloped, and devoid of resistive power There was strong evidence that in this country the commonest way of attempting abortion was by repeated, regular, and systematic purgation Among the drugs having a real or supposed poisonous action upon the fœtus itself lead in the form of diachylon took a prominent position It was taken in the north east of England in combination with aloes As a result of inquiries made among chemists and chemists' associations it appeared that diachylon was frequently asked for in the north by the lay public without the prescription of a medical man At least ten local associations of chemists had passed resolutions declining to sell it Evidence was forthcoming that herbalists sold the drug and did a regular business as abortionists. Among some of the measures which had been suggested for checking criminal abortion were the scheduling of diachylon as a poison and the notification of pregnancy Educative measures held out most hope of success and the greater consideration which was now being given to antenatal hygiene was encouraging A practical measure might be to make all abortions and miscarriages notifiable to the sanitary authority and to enforce a pathological examination of the fœtus and placenta in every such case

Dr **W G WILLOUGHBY** agreed that abortifacients might have a disastrous effect on the health of the child He feared that the scheduling of a few extra poisons would have little effect in restricting the use of abortifacient drugs At the root of the whole matter was the fact that a mother was not looked upon with the respect to which she was entitled People must be impressed with the danger arising from the use of abortifacients, and that if they were used healthy children might not be borne

Dr **SIDNEY C LAWRENCE** referred to the great difficulty in deciding whether lead or some other drug had been taken prior to an abortion

Mr **H H I HITCHON** said that in the north of England the use of instruments for producing abortion was much commoner than was realised A first step in stopping the practice was the prohibition of suggestive advertisements which opened the door to criminal practices

Dr **C W HUTT** asked what evidence there was that there was any injury to a child born after an unsuccessful attempt to produce abortion If the statement were incorrect it would do harm

The **PRESIDENT** agreed that some steps should be taken to prevent the appearance of the advertisements of abortioners and pointed out that abortifacients could be procured with the greatest ease from the very herbalists who were receiving payment from the State for treating patients insured under the National Insurance Act

EDINBURGH OBSTETRICAL SOCIETY

Presidential Address

A MEETING of this society was held on Jan 13th, Sir J **HALLIDAY CROOM** the President being in the chair

The following office bearers were elected for the present session —President Sir J Halliday Croom Vice-Presidents Senior, Dr G Keppie Paterson, junior, Dr Angus Macdonald Secretaries Mr E Scott Carmichael and Dr R W Johnstone Treasurer Dr John M'Gibbon Librarian Dr J Lamond Lackie Editor of Transactions Dr James Young Acting Interim Dr H S Davidson Members of Council Dr J Haig Ferguson, Dr D Berry Hart, Dr H S Davidson Dr G Barbour Simpson, Dr A H F Barbour, Dr W Fordyce, Dr P G Borrowman, and Dr J L Green

The following were elected Honorary Fellows of the society —Dr Cullen, Baltimore, U S A, Emeritus Professor Malins, Birmingham, Professor Briggs, Liverpool, and Professor Jacobs, Brussels

The **PRESIDENT** delivered his Presidential Address After thanking the society for the honour of being elected President for the third time, he proceeded to discuss the problems that were likely to occupy the obstetrician of the future The first problem was that of the scientific pursuits and achievements of women He passed in review the work of Madame Curie and Madame Henri, giving a résumé of the position which radium occupied in gynæcology The declining birth rate was dealt with, especially the investigations of Dunlop, showing the influence of delay of marriage in the size of the family, especially delay on the part of the woman Figures were quoted which showed, among other things, that comparing the average Scotch family with the corresponding figures for similar marriages 20 years earlier, the decrease in the size of the family was universal, and that for all ages under 36, age 32 excepted, that decrease amounted to more than one child per marriage He also dealt with the question of the relations between the working mother and the home, as far as the census figures illustrated them He showed that the mortality of the children of working married women was 62 per cent. higher than in the cases of mothers who were unemployed He proceeded to discuss serotherapeutics, with special reference to Abderhalden, and cognate problems were dealt with very fully He laid special stress upon prematernity beds, pointing out their value both from a scientific and a clinical aspect In conclusion, he dealt with the teaching of midwifery as it is carried out in the Edinburgh School

ÆSCULAPIAN SOCIETY —A meeting of this society was held on Jan 15th in the Metropolitan Hospital Dr David Ross, a past President, being in the chair —Mr Henry Curtis conducted a clinical afternoon In the absence of Dr E Cautley Mr Sylvester showed a boy, aged 14 suffering from Cerebro-spinal Meningitis On Jan 6th he vomited and had headache at 3 P M, mental confusion and drowsiness He was admitted on Jan 7th with headache groaning, and twitching of hands, chiefly left. He was semiconscious both pupils dilated, later on retracted abdomen Knee jerk plus, a scabies like rash Arms stiff, occasional twitching Temperature 100° F, pulse 84, respirations 30 Jan 8th Restless night Anorexia incontinence, head retracted tache Pulse 72, respiration 30 to 36 temperature 100° to 101° Jan 12th More conscious, takes food well, no spots Injection of 10 c c of Merck s serum Temperature 102° to 103°, pulse 100, respiration 34 Jan 15th Melæna with pain over sacrum on two occasions Temperature 103°, pulse 100, respiration 30 — Dr A Feiling mentioned a similar case in which the temperature was 89°, and never rose above 95° Patient who was comfortable all the time, died following morning —Mr Sylvester showed a man, aged 39 admitted on Dec 2nd suffering from Hæmatemesis On Dec 21st he developed right-sided parotitis On the 23rd gland subsided, but on the 26th was again swollen On Jan 8th pus was seen oozing from Stenson's duct after 1 in 8 acetic acid application to mouth Jan 15th, gland still very swollen and painful —In the absence of Dr W Langdon Brown Mr Sylvester showed the man of 38 years with Aplastic Anæmia shown at last meeting (Case 7), the improvement in his condition is apparent rather than real The quantity of blood is slightly less which is associated with a higher colour index and more red cells, the white cells show a higher percentage —Dr Leonard Williams showed 1 A soldier, aged 30 with greatly Enlarged Thyroid of ten years' standing, no signs of insufficiency After four months at the front the pressure of his equipment caused difficulty in breathing and swallowing He is improving under thyroid extract and potassium iodide 2. A girl, aged 19, with Graves's Disease the exophthalmos being of the flight and fright variety There

L Infection Puerperale Diagnostic, Traitement

By Professor CONSTANTIN DANIEL, Bucarest Paris A Maloine 1914 Pp 123

IN this monograph the author demonstrates that the condition known as puerperal septicæmia is in reality surgical septicæmia affecting the puerperal patient, and not in any sense a specific disease, and points out that this conception of the disease was originally put forward by Simpson in 1851 Although it is not possible to deny the occurrence of auto infection, yet it is certain that in the great majority of the cases the infection comes from without, and its entrance into the body is therefore preventable and should be prevented The two main forms of localised infection, generally with something retained in the uterus and generalised infection, are distinguished, and the great importance of a bacteriological examination is in every case insisted upon Clinically three types may be differentiated that in which the infection remains local, that in which it becomes secondarily generalised, and a third in which it is an acute general infection from the commencement, a true septicæmia. In considering the treatment of these cases the author recommends first an intra-uterine douche and then curetting With this advice most English obstetricians would disagree, they would prefer digital exploration first, with the complete evacuation of the uterus if necessary, followed by an intra uterine douche of some harmless fluid, such as sterile water, and no curetting The author discusses serotherapy and the various methods of producing leucocytosis, but nothing is said of the treatment by vaccines

The book forms a clear and interesting resume of the main facts that are known of puerperal infection, together with some informing statistics

Local Anæsthesia its Scientific Basis and Practical Use

By Professor Dr HEINRICH BRAUN, of Zwickau Translated and edited by PERCY SHIELDS M D, Cincinnati Ohio From the third German revised edition London Henry Kimpton 1914 Pp 399 with 215 illustrations in black and colour Price 21s net

Professor Braun's work upon local anæsthetics is well known in this country, and the latest edition of his book will be a welcome addition to the library for those who make use of the methods with which his name is associated The book is a very complete exposition of the principles and the practice of local analgesia is well printed and furnished with remarkably clear diagrams and illustrations Many of these are photographs taken at operations to illustrate various stages and processes in the performance of infiltration and conduction anæsthesia

The book begins with a history of the attempts to obtain satisfactory local anæsthesia from very early times up to the introduction of cocaine in 18[illegible] It is from that year that local analgesia begins in any form comparable with that with which we are now familiar Next comes a comprehensive survey of the work that has been done bearing upon the susceptibility to pain of the various organs and tissues of the body and a chapter upon the pain relieving action of nerve compression and anæmia Here it is made plain that the surgeons of old were right in attributing [illegible] anæsthesia to pressure on the [illegible] [illegible] is of only [illegible] In a chapter discussing the effect of osmotic tension of watery solutions the defects of tumefaction anæsthesia, or "anæsthesia dolorosa," are explained, and this method is denounced as practically useless The different local anæsthetic agents are discussed at length with the various methods of using them, and attention is paid to the symptoms and treatment of cocaine poisoning Braun endorses the usual opinion that there is no real antidote for cocaine Stovaine, according to his investigations, causes injury to tissues even in 1 per cent solution His final choice of agents is in favour of novocaine and alypine, tropacocaine and stovaine being reserved for spinal analgesia The two former meet all the requirements which he demands of a local anæsthetic, including compatibility with the use of suprarenin The influence of the vitality of the tissues upon the local and toxic action of anæsthetic agents is considered in a further chapter, and then the technique of operations upon various parts is gone into in detail and supplemented with excellent illustrations

The book may be fairly regarded as a complete and masterly account of local analgesia

Urgent Surgery

By FELIX LEJARS, Professor Agrégé à la Faculté de Médecine de Paris &c Translated from the seventh French edition by W S DICKIE F R C S Surgeon North Riding Infirmary Middlesbrough. Third English impression Vol I Introductory Head Neck, Chest Spine Abdomen Bristol John Wright and Sons 1914 Pp 614, with 20 plates and 1085 illustrations Price 25s net

THE seventh French edition of this well known work was reviewed in these columns so recently as Sept 19th, 1914, but this, the second English edition, deserves a fresh set of readers in this country For their benefit it may be stated anew that the author takes a wide view of the term "emergency" that he speaks precisely and definitely but not didactically, drawing upon a vast experience, and illustrating his text with brief but lucid case reports

Injuries of all types naturally figure largely in the chapter headings, which indicate the comprehensive character of the text Subcutaneous injuries of the chest for example take six pages, whilst wounds of the thorax need 40 The section on wounds of the pericardium and heart is well illustrated, and embodies the cream of extensive recent literature in addition to the author's personal experience, even gastrostomy and jejunostomy are included, which as we all know ought not to be, but not infrequently are, surgical emergencies Additions in this edition deal with acute dilatation of the stomach, acute pancreatitis, obstruction of the mesenteric vessels, sigmoiditis, and perisigmoiditis

Whilst this book is certainly one to be read by the junior surgeon to prepare him for prompt action in moments of emergency, and may in ideal conditions be available for reference at such times it has in addition altogether another value Most surgeons have very poor records of their most interesting operations for these are of necessity performed in moments of stress A volume such as this read at leisure will enable the busy surgeon to recall his experiences and to collate them with the author's Much indeed of the text is only to be fully appreciated by those well versed in practice [illegible] offers [illegible] means of consolidating knowledge with gain in precision and utility In this light the chapters on abdominal surgery may be read with all [illegible] opinion of the evolution. Having stated in a previous book that "adaptation" (that all-important fact in the view of the selectionist) "needs no explanation," he writes the present one to defend this statement by an endeavour to show how the need for such an explanation has arisen and why it seems unnecessary The author's position, shortly stated, comes to this Adaptation is the primary attribute of living things, and therefore, as an unadapted thing could not live, it is its own explanation But there is a resemblance between organisms and mechanisms in that they both possess the attribute of adaptation, and because man, the chief maker of mechanism, does not regard himself actually as life, but holds himself apart from it, he wonders, makes for himself a problem, and says, "How is it that life can produce the same kind of results that I myself can produce?" And so men, impelled by this wonder alone, proceed to invent theories, one of which is that of natural selection.

It may be held that the author's statement of his position is its own condemnation, so great are his misconceptions of the attitude of science towards the search after causes, and so erroneous are the assumptions involved in his position But, apart from this, he indulges in much word play in his desire to show that it is unreasonable to seek for any explanation of "adaptation", and frequently misrepresents the position of those whom he is opposing Against the selection theory, for instance, he argues that it is "not science" and should not be taught as such because it cannot be appreciated by all, but only by those "who need a *final* explanation of life" Whether by "final" he means here the *final cause* of life (which words, if correctly used, would stand for the object or purpose for which life came into being) or the *efficient* cause of life and how it arose, his allegation that the selectionist especially must necessarily desire a final explanation of life is hopelessly beside the mark The scientific man seeks for no final cause, or ultimate explanation of anything, least of all for an ultimate explanation of existence All ultimate problems are inscrutable and have nothing to do with science But science can and does seek for answers to questions such as this By what method has organic evolution been brought about?

It is needless to criticise in detail the chaotic logomachy which marks this book, but its quality may be illustrated by a few excerpts "The growth of science is different from the growth of man's perceptive ability, which is evolution." "We shall continue to explain life for the very reason that it has no (final) explanation We shall understand it more and more, simply because we shall never be able to understand it completely' "If the human intellect, which is a part of life, were to understand life, the part would, as it were, grasp the whole, which seems impossible"

The book ends with an advocacy of Bergson's philosophy and of the doctrine of "discontinuity" according to the Mendelians and mutationists The author, however, says that he has "no wish to urge the reality of discontinuity, but only the practical advantage and necessity of admitting it" In denying that the theory of natural selection is scientific the author revives the old and erroneous charge that the theory is equally teleological with that of special creations Against all such "teleology' he opposes the theory of "vitalism," from the point of view of which (he says) it is inconceivable that we should know the cause of life and evolution, and thus he makes short work of biological science It must, however, be borne in mind that, anti teleologist and anti mechanist in one as he professes to be, he espouses the mutationist biology and the Bergsonian philosophy—doctrines which have been widely welcomed either by religious persons to whom natural selection is unpalatable, and who see in mutationism an approximate return to the theory of special creation, or by modern mystics of many colours who frame assumptions and style them discoveries

The whole trend of the author s dialectics establishes his own statement that this book "is not scientific in the usual sense" We venture to add that it is not scientific in any sense

A System of Surgery

Edited by C C Choyce, B Sc, M D Edin, F R C S Eng, Dean of, and Teacher of Operative Surgery in, the *London School of Clinical Medicine (Post-graduate)*, &c. Pathological Editor, J Martin Beattie, M A., M D, C M Edin, Professor of Bacteriology in the University of Liverpool, and Bacteriologist to the City of Liverpool In three volumes Volume III With 12 coloured plates 22 black and white plates, and 242 illustrations in the text London, New York, Toronto, and Melbourne Cassell and Co, Limited 1914 Pp 901. Price 21s net

The third volume of this System of Surgery maintains the high level of those that have appeared previously It deals with important subjects The account of the surgery of the cardio vascular system, which is by Mr Rock Carling, is clear, but we think that it would have been well to say a little more about the surgery of the heart Mr J F Dobson has contributed the description of the surgery of the lymphatic system, and this chapter includes Hodgkin's disease Mr Arthur Edmunds is responsible for the section dealing with the surgery of the neck, including the surgery of the thyroid and the thymus glands He holds the view that the parathyroid glands are not merely undeveloped thyroid tissue, but that they have a separate function, and that their removal leads to the production of tetany

The chapter on the surgery of the nose and accessory sinuses, by Mr Harold Barwell, contains a plate which shows well the transillumination of the antrum and the frontal sinuses Mr J Stoddart Barr's article on the surgery of the ear, pharynx, nasopharynx, and larynx is good and it is elucidated by some useful illustrations of the anatomy of the ear, though they are on rather a small scale Sir StClair Thomson has described the direct examination of the lower air passages and of the œsophagus Space does not allow us to notice in detail the different divisions of the work, but we may mention that the chapter on the lungs and pleura is by Mr H Morriston Davies, that on injuries and diseases of nerves by Mr James Sherren, that on the scalp, skull, and brain by Mr Wilfred Trotter, that on the spine and spinal cord by Mr Wilfred Trotter and Mr Gwynne Williams, that on the surgery of the jaw by Mr D C L Fitzwilliams, that on the skin and subcutaneous tissue by Mr T P Legg, that on the surgery of muscles, fasciæ, and tendons by Mr Rock Carling, that on bursæ by Mr E D Telford, that on bones and joints by the Editor, that on fractures and separation of epiphyses by Mr Albert J Walton, and that on orthopædic surgery by Mr R P Rowlands The names of the authors are a sufficient indication of the value of the chapters they have written All can speak with authority

THE LANCET.

LONDON SATURDAY JANUARY 23 1915

The War and Nervous Breakdown.

AN increase in the number of nervous troubles is naturally to be anticipated during the time of war All forms of nerve instability will certainly receive fresh impetus Recrudescence of dormant weakness is sure to occur under the additional strain involved in long continued personal anxiety combined with the weakening influence of fatigue and, perhaps, economy of food The loss of central control during an engagement has often been depicted in art galleries, and the conception of the artist is abundantly confirmed by the extracts from letters from the front which have been appearing in many of our contemporaries The overmastering interest of the time of engagement does not persist in normal individuals With the relief of the immediate strain of conflict the organism speedily regains its normal tone, and though there may be a fleeting return of excitement during the narration of experiences, no harm results so long as the individual is not haunted by the past both day and night This is, however, only true for the majority of previously healthy young adults who have been in the firing line Neurologists state that they are being consulted by an increased number on account of many nerve symptoms of an ill defined character Some of these cases present symptoms analogous *to those* of milder forms of epilepsy, and on investigation it may be *found* that during infancy or adolescence similar *symptoms had been present* Far more frequently an accurate diagnosis is *not* possible, or, at least, a diagnosis which will harmonise with any definite lesion The condition resembles that which has long been familiar in the law courts in claims after railway accidents, to which it has been convenient to apply the term "shock"

Although many features *of the* present war will impress future generations with a sense of horror *there* are also happily, many comforting reflections to be *derived* from observation of our national characteristic trend of thought It is distinctly cheering to note how eagerly each possible new development *is* appreciated, as measures are devised for dealing with each contingency on reasonable lines *From the* outset of the war it was evident that one problem would be the judicious treatment of nervous *symptoms* The early arrival of men who had been through all the weariness of the [illegible] marches with insufficient sleep, gave [illegible] that it could not be disregarded *Lord* [illegible] drawing conclusions from the condition of those reaching the London Hospital, appealed for funds to establish an institution for the treatment of cases of shock His appeal met with ready response, which has permitted the opening of a special hospital for officers, equipped for the reception of 35 patients We learn that it is at the instance of the War Office that this undertaking has been restricted to officers, but it would seem possible that ere long something of a similar nature may be required for the treatment of the rank and file At the moment of writing this question is under discussion by numerous voluntary helpers, and it is uncertain whether their conclusions or recommendations will be of a nature to secure official approval No doubt steps are being taken to determine whether the generalisations drawn from a limited number of cases in the early days of the war are supported by further observations It is essential that this question should be decided before it is worth while formulating elaborate schemes likely to entail considerable expenditure Amongst the soldiers who have been through the harassing time in the trenches there are certainly some whose condition appears to call for the utmost consideration and patience They are sleepless, or sleep in short snatches disturbed by frequent nightmares They are dull and depressed, and they are unable to take interest in their surroundings This dreary picture of apathy is said to be strongly suggestive of the usual premonitory symptoms of chronic mental degeneration, familiar to those who work among the border line cases, which so often end in melancholia or in delusional forms of insanity While, however, this is true of some officers, so far, we believe, it has been comparatively rare among the men of the rank and file The latter, although submitted to the same bewildering tumult of noise and to similar short hours of sleep, do not appear to suffer to the same extent as the officers, who, in addition, have to experience the continual strain of heavy responsibility All accounts favour the conclusion that among the men it is rare to find that the apathetic condition persists, or that it leads to more permanent mental changes

It would perhaps be rash to assume that the men possess a greater reserve of recuperative power than their officers, *or to* infer that their restoration is due to lack of imagination *or* want of memory, but all observers agree that just as they take their discomforts in the trenches in light hearted fashion, so they go through hair breadth escapes with cheery optimism Even some of those who seemed most depressed on *their* return to this country speedily recovered tone, after sleeping almost continuously for 48 hours The point which has to be determined, however, is whether all cases of nervous breakdown will really pursue such a satisfactory course and what is to be done with those who still show signs *of instability* long after they have

"Arabian Nights' Entertainments", and this leads us to one querulous complaint the paper is so highly glazed for the sake of the illustrations that in artificial light the letterpress cannot be seen at all at some angles This, to be sure, is but a trivial fault in a book of solid worth It is due to the translator to say that his work has been extremely well done, the text reads as if composed in sound English

Précis de Chirurgie de Guerre

Par EDMOND DELORME, Médecin Inspecteur Général de l'Armée Paris Masson et Cie 1914 Pp 230 Price 4 50 francs

IMMEDIATELY after the outbreak of hostilities the author delivered an address at the Institute of France on the leading principles of surgical treatment in the field and on removal to hospital This was received with great applause and has been circulated widely by the War Ministry amongst the medical officers of the army and of the hospitals where military patients are received throughout France Dr Delorme, in spite of incessant and laborious military duties during the last three months, has been able to put together in a very handy and compact form all that is necessary for a military surgeon to know in regard to wound treatment Extreme brevity and clearness of expression, with precise directions as to what must be done and what should not be attempted in the treatment of wounds, are the distinguishing marks of the book This is just what is wanted by the surgeon on active service There are a few illustrations The number of these might have been usefully increased, but the circumstances of the production of the book are probably the reason for the absence of some A short description is given of the weapons and of the projectiles used in modern warfare, after which wounds are dealt with, first according to the tissues and then according to the regions affected The author rightly insists that the field dressing must be properly applied by the surgeon or his assistant, not by a soldier or a comrade, "mieux vaut ne pas panser une plaie que de la mal panser," otherwise there is no security against infection. Tincture of iodine (1 in 20) is the disinfectant used Dr Delorme especially emphasises the almost uniformly conservative tendency of modern surgery

JOURNALS AND MAGAZINES

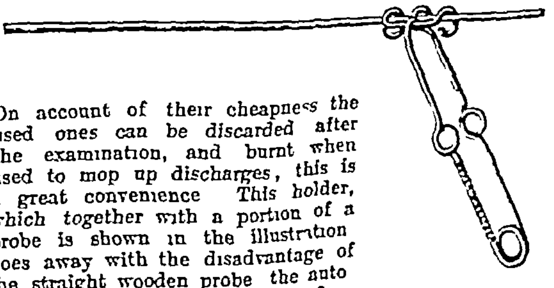
The American Journal of Tropical Diseases and Preventive Medicine Vol II, No 6 (December, 1914)—Dr Isadore Dyer writes on venereal diseases considered as a public responsibility, and points out that although provision is made for such cases in some general hospitals, in most of them these affections are endured and not invited He thinks that it is not extreme to say that nothing at the present time is more menacing to society than the prevalence of syphilis and gonorrhœa, and no demand is so urgent as that of adequate protection by proper hospital provision The present method in the United States as elsewhere makes the victim of venereal disease secretive and neglectful by surrounding treatment at a public institution with such an atmosphere of incrimination that the patient applies for medical relief only as a last resort Dr Dyer therefore pleads for separation of the medical side of the question from the moral and social and he urges that venereal diseases should have the place in the hospital plan which their importance demands — An article on Human Filariasis is contributed jointly by Dr Allen J Smith and Dr Damaso Rivas containing a relation of certain observations carried out by them during the past four years on patients suffering from filariasis in the Laboratory of Comparative Pathology and Tropical Medicine of the University of Pennsylvania A series of experiments were also carried out with bed bugs to test the suggestion that this insect might act as the intermediate host of the filaria bancrofti Although microfilariæ were found in the body of the bed bugs after they had been fed on two infected patients (both of them students from Porto Rico) and although the microfilariæ lived in the body of the bed bugs up to the eighth day, no evidence was found of development taking place It is, moreover, questionable if larval development is possible in the bug But, nevertheless, the chance of finding filarial embryos in these insects in houses where filarial patients have passed the night is at least of interest and might perhaps occasionally be of practical importance —Dr H C Clark, of the Ancon, Canal Zone, Medical Service, gives an analysis, with copious details, of 37 fatal cases in which pellagra had been diagnosed either alone or in association with other diseases Histological, bacteriological, and inoculation observations offered no data that would help to reveal an etiological factor, or to prove that the disease was a separate entity There was a striking association of pellagra with such diseases as syphilis, chronic alcoholism, arterio sclerosis, starvation, chronic pelvic inflammation, and various types of chronic intestinal inflammation, and it would appear possible that this syndrome might frequently be a sequel to the above named conditions —News and comments on passing events along with reviews of current literature, complete the number

Eugenics Review, January, 1915 —In men and in money the present war will exact a toll the effects of which will be felt long after peace has been declared That racial qualities must be affected is equally certain, and any contribution which may help towards a solution of the many problems which will confront us in regard to the well being of the race should receive attention In an article entitled Eugenics and the War, Mr Theodore G Chambers discusses from the point of view of the inevitability of war its racial effects He quotes the opinion of many writers on the subject, and the conclusions are necessarily somewhat indefinite. The Measurement of Intelligence, by Dr T Simon translated from the French by Dr W C Sullivan, is another paper dealing with a subject which is attracting much attention.

New Inventions.

AN IMPROVED PROBE-HOLDER

WOODEN probes are very useful in nasal and aural work, and especially so when used as wool carriers



On account of their cheapness the used ones can be discarded after the examination, and burnt when used to mop up discharges, this is a great convenience This holder, which together with a portion of a probe is shown in the illustration does away with the disadvantage of the straight wooden probe the automatic clip can be released, and a new one inserted without soiling the fingers The instrument has been carefully made for me by Messrs Mayer and Meltzer, Great Portland street London, W

THE GALTON LECTURE —The Galton dinner and lecture which were instituted last year by the Eugenics Education Society in honour of the memory of Sir Francis Galton, F R S will be held this year, as before on the anniversary of his birth Tuesday Feb 16th, at the Hotel Cecil at 7 P M Professor J A Thomson will deliver the lecture, which will deal with Eugenics and the War refuge of a scoundrel" The argument which the agitators employ is that the idea of inoculation is a bar to recruiting Of course, the idea only becomes a bar to recruiting among those who have been filled full with falsehood The man who wishes to serve his country, for the sake of himself and his comrades should be willing to undergo discomfort rather than risk the introduction among the troops of the ravages of a disease which in the past has caused so many deaths For if a man contracts typhoid fever he is a danger not only to himself but to those who are associated with him Some inconvenience for a day or two is nothing as compared with an attack of typhoid fever, to undergo an infinitesimal—nay, a negligible—risk in order to help in the maintenance of a healthy army is what is required of the recruit but this is not the way in which the situation is described by the authors of these circulars, who are thrusting on the public their ill informed pathology by advertisement also No words are too strong in condemnation of those who under the guise of patriotism are seeking to force their own fads, founded upon ignorance, upon our prospective troops to the detriment of the future of the nation

It is evident that the dissemination of these circulars in a broadcast way may prove a distinct danger to the State, and the danger is exaggerated when advertisements in support of the attack upon recruiting are accepted by a national institution like *Punch* Authority has been given to the Press Bureau to prevent anything being published that will act in a detrimental manner to the course of the war The action of ignorant fanatics in attempting to influence our recruiting, and to persuade those in our army to refuse to follow a preventive treatment which the highest medical authorities recommend, is surely detrimental to the cause of the Allies, and we strongly urge the authorities to take all the necessary steps to prevent the publication of pamphlets and advertisements spreading misleading statements on such an important matter as inoculation against typhoid fever The misuse of the term paratyphoid" in the advertisement which appeared on Jan 13th last in *Punch* (and whose insertion our contemporary has now stated to be due to accident) in itself shows the want of knowledge on the part of the persons who are responsible for public statements that the recruits are being treated with tyranny and ingratitude, and that inoculation has been proved to be "an utterly useless and dangerous practice

The recent letters to the *Times* of Sir WILLIAM OSLER and Sir LAUDER BRUNTON form a praiseworthy summary of the situation, and the former's appeal to soldiers in two final questions should have as wide a circulation as possible The questions are —

1 Will you, between the statements of misguided cranks who may [illegible] in the enemy's hands by perverting their [illegible] will you [illegible] listen to men who have devoted their lives to the service of humanity and who have no wish in the matter other than your good ?

2 Against a transient indisposition will you put in the balance the chance of a protracted and costly illness, possibly an untimely death ?

As soon as possible the publication of the statistics of the results so far observed as regards the value of inoculation during the present war should be published No official pronouncement has as yet been made, but it is significant that the French military authorities are stated to be so satisfied with the value of inoculation that army surgeons are sent to the front to vaccinate a whole army corps in the firing line It is further stated that arrangements are being made to inoculate every soldier whether at the front or at the depôts in the interior of the country Whether compulsory inoculation should be introduced into our forces is a question which has no doubt been seriously considered by those responsible for the health of our armies, and doubtless if they decide to introduce such a measure they will be entirely uninfluenced by idle chattering

Annotations.

"Ne quid nimis"

THE AIR RAID

ON Tuesday evening last an air raid took place over the east coast of England, when bombs were dropped into Great Yarmouth, Sherringham, and King's Lynn, confirming the probability of such attacks upon unfortified places So far it is only coast towns that have suffered, whether from raids by sea or air, but while, of course, only such towns can be subjected to shell fire from sea, inland communities, if fortune fights on the side of the attack, can be harassed by missiles from the air It would be childish to point this out were it not that some among us appear to forget it, and their behaviour is as troublesome as that of those who can think of nothing else The raid on the Norfolk coast is a complete answer to those who have grumbled without cease at the atmosphere of depression created by placing London for so long a period in gloom—a gloom which has been accentuated to the point of darkness recently, as information concerning the German intentions grew more complete Those communities which by their geography or their importance invite the attention of the enemy must be prepared for attacks by air, and if we can all imitate the brave calm of Norfolk under trial the attacks will fail in their principal object, whatever miserable toll of life they may exact We do not minimise the anxieties, and in a few sad cases the anguish, caused by air raids on our coast when we say that no serious damage can be done by them to the general military situation But in densely populated settlements of which London is the greatest example in the world, the loss of life following such attacks might be terrible We would urge the citizens of great cities at the first warning of the approach of danger to obey such authoritative advice as they have as yet received—advice which calls attention to the danger from fragments of the shells and bullets fired by our guns used against hostile aircraft.

been removed from the active line Some such cases are certainly hopeless, but there are others, and happily these are in preponderating numbers, where there are good grounds for believing that they may again become useful citizens In these more prolonged cases it is in the highest degree improbable that they can ever be employed again on active service They are so far shaken that they could not be trusted in emergencies They might be of use in the army in times of peace, but having lost nerve they could never be sent to the front again While the outlook in these cases is thus limited, it is to be hoped that the authorities will see their way to some form of treatment which will not hamper the future by the infliction of a stigma. Admitting that they bear all the appearances of border line cases it would be regrettable if they were sent to public institutions as though they had already crossed the border The difficulty of finding employment for those who have been discharged from the service as unfit is already great The difficulty should not be increased by adding the stigma of retention in a lunatic asylum unless there have been unmistakable grounds for this course We mention these things hopefully, for during the administration of Sir ALFRED KEOGH there have been abundant indications that the medical department of the War Office is acting with due consideration for individuals, and for the welfare of the community, as well as for the prosecution of the war to a successful issue

◆

Antityphoid Inoculation

THE agitation which has been engineered in certain quarters against antityphoid inoculation has drawn public attention to a prophylactic measure the utility of which has been proved for all minds capable of appreciating what proof is, but misrepresentations made with sufficient reiteration and vehemence produce upon ignorant people impressions which are hard to remove Evidence is accumulating in all parts of the world demonstrating the good results which have followed the adoption of inoculation against typhoid fever The large number of deaths which occurred in the South African War well illustrated the ravages of disease during campaigns where preventive measures were imperfect, but we got little therapeutic instruction from the tragedies which ensued There were 57,684 cases of typhoid fever, of which 19,454 (33 per cent) were invalided and 8022 (13 9 per cent) died. Although inoculation had been introduced at that time the conditions under which the treatment was employed made deduction from the results unsafe The technique has since been considerably improved, and the experience of other nations has made clear the beneficial effects of preventive inoculation Sir W B LEISHMAN in a letter in THE LANCET of August 22nd, 1914, instanced the fact that about 93 per cent of the British garrison in India have been protected by inoculation, and the disease which used to cost the nation from 300 to 600 deaths annually was last year responsible for less than 20 deaths Again inoculation was made compulsory in the American army in 1911, it having practically abolished the disease in American stations, in 1913 there were only three cases of typhoid fever in the entire army and no deaths In Japan also encouraging figures have been obtained In short, all experience goes to prove that inoculation against typhoid fever is a most valuable adjunct to the health of an army It must not be asserted that it is an infallible protective—that is to say, that a man who has been inoculated is proof against infection That would be adopting a view which cannot be supported by clinical evidence, and might easily give a false impression to the general public, and so play into the hands of the enemies of research But inoculation does confer a very considerable degree of immunity against typhoid fever, and the disease in the inoculated person is of a far milder type than in the unprotected These two things would constitute a sufficient cause to urge the free adoption of the measure Inoculation, however, does more than this it greatly decreases the incidence of the malady

Medicine is regularly attacked by those quite ignorant of medicine In regard to a knowledge of (say) physics, law, or military tactics, the public at large, as a rule, pay deference to those who have made a life long study of a particular profession, but towards medicine the public to some extent adopts a different attitude, and upon occasion there is a reasonable basis in this attitude, for a man has naturally a feeling towards his body that he has not towards his possessions or his civic privileges Well aware of this feeling, agitators have shown their hatred of scientific medicine in a manner difficult to combat, but very likely to obtain recruits from the ignorant, the timid, and the sentimental Physicians and surgeons who have devoted themselves to a study of disease, its cause and prevention, are quite used to being contradicted by these sort of people, and as a rule only resent the treatment when the general health of the community is in question Consequently faddists are listened to and believed who have had no opportunities of studying the intricate problems of morbid processes, and their opinions are quoted seriously against those of members of the medical profession who have devoted long years to special work At the present time a course is being pursued in connexion with inoculation against typhoid fever which well illustrates the danger of allowing unlimited license to antiscientific agitators A quantity of "literature" is being widely disseminated, containing garbled statements and misrepresentations which can only have an unhappy influence upon a large number of those who read them The pamphlets or circulars are couched in term of patriotism, and came to us in one case accompanied by a little publication, humorously quoting Dr JOHNSON as saying that "patriotism is the las the atlas was reached The incision was then carried through the left lateral occipito atlantal ligament until a small blackened area was found surrounding the bullet Removal was difficult until a good grasp of the bullet was obtained with toothed clamps, because the bullet was wedged beneath the arch of the atlas and there were a few sharp projections on it which were produced in its transit through bone A rubber drain was inserted and the muscles were sutured with chromic gut and the skin with silkworm gut Recovery from the operation was uneventful. The child was kept flat on his back and not allowed to move his neck for two weeks When he was discharged on the twentieth day the wound was solidly healed, but there was considerable stiffness of the neck, particularly for backward movements of the head and rotation from left to right A month later movement was freer, but was still limited in the directions mentioned An interesting point is that the bullet entered the spinal canal in front between the base of the skull and the atlas, and was extracted from the canal in the rear, and yet the cord apparently was uninjured

A NEW METHOD OF STERILISATION

Dr Guido Cremonese, in a recent issue of the *Gazzetta degli Ospedali*, draws attention to the value of iodobenzine as a disinfectant It is prepared by pouring some tincture of iodine into a certain quantity of benzine, the excess of tincture of iodine sinks to the bottom and a saturated solution of iodobenzine is formed Gratifying results are claimed for its use, first for sterilising the hands, it being sufficient to rub in a small quantity, secondly, as a ready method of preparing dressings by soaking them in the solution which is then allowed to evaporate, and thirdly for sterilising wounds by the application of tampons medicated in this manner The author states that with the antiseptics in common use some time is required to render a septic locality sterile Iodobenzine, on the contrary, has a rapid and immediate action by means of irradiation of nascent iodine vapour by the rapid evaporation of iodine and benzine The antiseptic action is therefore developed at once while after a few minutes a simple sterile dressing remains in contact with the wound

THE CHEMISTRY OF RICE POLISHINGS

THE curative substance of rice polishings is still resisting analytical attempts to isolate a definitive principle Some recent work by J C Drummond and Casimir Funk upon this subject is recorded in an interesting paper published in the December number of the *Bio chemical Journal* These workers carried out an exhaustive fractionation of the phospho tungstic acid precipitate from an alcoholic extract of rice polishings They confirm the presence of considerable amounts of choline and nicotinic acid in the polishings and betaine adenine guanine, and possibly guanidine were detected Small amounts of other substances were isolated but in quantities insufficient for identification The work of the Japanese authors Suzuki Shimamura and Odake who claimed to have isolated the curative [illegible] in the form of its picrate was repeated, but the results did not lead to any confirmation of the work of these [illegible] While Drummond and Funk failed themselves to isolate the curative substance which occurs in rice polishings, they are inclined to think that it is decomposed during the fractionation process, when all trace of it is lost From this it would appear that the so called vitamine is a readily decomposed base and it would be interesting to discover what happens to its nitrogen in the processes of nutrition Usually inert, nitrogen may in a nascent state prove to be an activator

DEATH AND THE ADRENAL GLANDS

IT is probably a unique observation in morbid pathology that there exists one particular organ, the adrenal gland, careful examination of which can indicate with tolerable certainty the manner or mode of death With the particular disease responsible for the *exitus* the condition of the gland may have less immediate concern To explain the relation of this gland the following facts may be noted Of the two parts of the gland the cortical constituting 80 to 90 per cent bulk of the organ, stores a lipoid material, the medullary portion secretes adrenalin It is with this latter function that we are immediately concerned An intimate physiological relationship exists between the nervous sympathetic system and the adrenalin gland content which controls the vascular tension An effective supply of adrenalin ensures an efficient circulatory and general tone, diminution leads to fall of blood pressure and asthenia The estimation of the gland adrenalin content after death shows important changes, and it is these which indicate something of the conditions preceding death Dr T R Elliott[1] has examined the glands from the point of view of adrenalin content in 80 cases (the lipoid was estimated in 170 cases) The first fact brought out was that no relationship could be established between the particular disease and the adrenalin content, nor was there any definite relationship between cortex and medulla But an important difference in content was noted when the mode of death was inquired into Sudden death, due to whatever cause, showed a practically normal adrenalin content, where however, general distress preceded death, a marked loss of secretion in the gland was noted For instance, the gland content in a case of sudden death was 4 5 mg (a normal figure) in a heart case with slow failure and apathetic death 2 3 mg, in another heart case with acute failure and mental distress, 0 2 to 0 7 Prolonged anæsthesia may induce similar changes—e g, long anæsthesia, 2 to 3 0 mg That adrenalin exhaustion follows strains imposed upon the nervous system has been abundantly shown in experiments, and that the gland is 'emptied' as it were of adrenalin by splanchnic nervous channels has been shown in cats, where, on splanchnic supply being cut off, the gland it supplies is not affected under exhausting general conditions which "empty" the opposite normally innervated gland The adrenal glands are played upon by emotional and vasomotor reflexes as frequently as are the muscles of the blood vessels themselves In such a crisis as impending death from diphtheria intoxication, for instance there is an urgent demand by the individual to combat the fall of blood pressure and other changes elsewhere To maintain the vascular tone the adrenalin is called upon and we find as a result

---

[1] [illegible]

The streets should be avoided by the populace when it is known that an air raid is imminent, as being the really dangerous place There is nearly as much chance of a bomb dropping in a street as on a building, while the streets will necessarily be exposed to the missiles of the defending guns In the metropolis and in some other large towns medical precautions have been taken in case of air raids, and the necessity of the general population taking cover is always assumed in these arrangements In London plans have been made with the full approval of the police for the immediate dispatch of surgeons to the spot in the event of any terrible emergency, and, moreover, a scheme has been carefully thought out whereby first aid will be rendered in harmony with the police to any sufferers from an air raid, all local men assisting in rendering the necessary help before the wounded are removed to hospitals or other institutions We hope that other great cities have organised some plan for making use of their medical inhabitants This should be done at once, for there will be no certainty, and generally no possibility, of summoning medical aid to a given spot after the tragedy has occurred, when there will be few lights, consequent difficulties of transport, and perhaps disorganisation of telephone and telegraph

THE SCHEDULE OF POISONS

THE law relating to the sale of poisons is continually a source of disquiet to the public conscience Upon the occurrence of a fatality due to a poison, whether the result of accident or design, in all probability the scope of inquiry will include considerations of purchase Coroners' juries seem never to weary of calling the attention of the proper authorities to the need of imposing additional restrictions on the sale of poisons It is not always clearly understood who these authorities may be or what difficulties may stand in the way It is felt that the safeguards provided by law are defective, and it is more judicious to kick the law, an impersonal, nonsentient organism, than to pass a resolution of censure upon some unfortunate wight who has been outwitted As the law stands poisons are divided into two groups, Part 1 and Part 2 of the schedule, and the restrictions imposed in the case of any particular drug or poisons depend upon the place assigned to it in the schedule The obstacles in the way of sale to the public are greatest with regard to all poisons included in Part 1 of the schedule Frequently complaint is made that these regulations are unduly troublesome to the vendor, and protests are raised when any additions are made to the list, even though the need of such additions has been emphasised by repeated misadventures, as was notable in connexion with veronal and hypnotics of allied chemical composition It is generally assumed, when there has been delay in the inclusion of new poisons in the schedule, that the fault lies in the intricacy of the steps by which the change is to be effected This is not strictly true, though the recommendations have to receive the approval of certain public officers after they have been transmitted from the Pharmaceutical Society To judge from recent pronouncements it would seem that the reasons for delay are more intimately connected with an amiable desire to meet the demand for the articles We have noted that the alteration in the strength of the official tincture of opium has had the effect of bringing it automatically within the scope of Part 1 of the schedule, which includes opium and all preparations or admixtures containing 1 or more per cent of morphine While no objection has been taken to the alteration in strength, there has been an outcry against the retention of the synonym "laudanum," since it appears that under this name the drug has hitherto been freely sold in small or large quantities The matter has been deemed of sufficient importance for the Pharmaceutical Society to seek the advice of its Law Committee and it has received and adopted the following report —

> That the policy to be advocated by the Council in regard to the sale of laudanum should be that when "laudanum" is asked for the 1914 preparation should be supplied and the poison book signed, but where the 1898 preparation is demanded care should be taken to label accordingly and the attention of the purchaser should be called to the fact that it is the 1898 preparation

It would be interesting to know how often we are likely to meet with a member of the public who has any notion of the difference Probably the majority will ask for what they have been in the habit of using, and if tinctures of both strengths are kept, the one will be reserved for the emissary from the local inspector, the other, with a few words of explanation, will be supplied to the public as before There is always danger in keeping preparations of different strengths with similar names, and it is to be hoped that this suggested system of meeting the demand for the sale of a remedy which may become a poison if improperly employed, will speedily be rescinded Meanwhile it is curious to note that in Ireland opium and all preparations of opium or of poppies appear in Part 2 of the schedule, which means that though they require a label stating the name of the article the word "poison," and the name and address of the seller, it is not necessary in Ireland to make any entry in the poison book of the date of the sale, the name and address of the purchaser, the name and quantity of the article sold and the purpose for which it is stated by the purchaser to be required Comparison of the schedules of Great Britain with those of Ireland reveals several other inconsistencies and affords strong reasons for suggesting that the two should be brought into harmony whenever it is possible to devote attention to the subject

REMOVAL OF A BULLET FROM THE ATLAS

IN the *Boston Medical and Surgical Journal* of Nov 26th, 1914, Dr F H Lahey has reported a case in which he performed the unusual operation of removing a bullet from the atlas The patient was a boy, aged 8 years, who, while sleeping, was shot by a demented parent The bullet entered the left side of the upper jaw just above the second incisor tooth, penetrated the hard palate near its junction with the soft, and entered the posterior pharyngeal wall The X rays showed the bullet lying inside the posterior arch of the atlas on the left side, just behind the groove for the vertebral artery On the next day the boy was taken to hospital An immediate operation was not performed on account of sloughing of the wound of the palate and because the bullet was causing no symptoms After three days, when much of the slough had separated, a curved incision was made from below the external occipital protuberance to the mastoid process The incision was deepened through the cervical muscles as in performing suboccipital decompression, until the posterior arch of of the Fannia scalaris The patient had voided similar objects on Oct 19th and 28th, but had not brought them, fearing he would be laughed at He lived on a farm and was in the habit of micturating into a glass which he kept in a shed turned upside down and which he always rinsed after using He used a syringe of hard rubber for urethral injections This he kept wrapped in paper in a closed drawer Apparently, therefore, the larvæ could not have been derived from the glass or the syringe About 8 o'clock in the morning while digging he was seized with an intense desire to micturate, he hurried to the shed, felt something pass with the urine, and found the larva in the glass He did not see it move When Dr King received it two hours later it was in a perfectly fresh condition The patient could not find any larvæ in the fæces after a diligent search Dr King thinks that the urethra was probably infected while the patient was at stool, flies being attracted by the urethral discharge In Chevrel's case the patient was a paralytic woman, aged 55 years, who was left alone all day on a chair which had been converted into a commode, the receptacle for the dejecta being placed on the floor Flies were able to swarm freely about the buttocks For about two months she daily passed larvæ with the urine Chevrel thinks that while dipterous ova may be carried into the urinary passages by sounds or catheters or in water used for irrigating, they generally are deposited about the meatus urinarius, where are found the conditions favouring their growth—namely, darkness, moisture warmth, oxygen and food, the last being furnished by a gonorrhœal or other discharge The eggs hatch promptly, and the young larvæ pass into the urethra and bladder in search of food They require but little oxygen, for Chevrel kept them under water for hours and found them still active when taken out Infection is favoured by sleeping in hot weather with the genital region uncovered

Brevet Colonel William Heaton Horrocks, R A M C has been appointed Honorary Surgeon to the King, in the place of the late Surgeon Major General Sir John By Cole Reade, K C B

THE second volume of the annual report of the London County Council for the year 1913 has just been issued and comprises the report of the Asylums Committee for the year 1913-14

Dr Llewellyn P Phillips, professor of medicine at the Cairo Medical School, has been appointed Physician in Ordinary to S M the Sultan of Egypt

THE Executive Committee have appointed Dr J A Murray to be Acting Director of the Imperial Cancer Research Fund

---

DEATH OF A VETERAN SCOTTISH PRACTITIONER.—The death of Dr Robert Leys took place at his residence [illegible] on Jan 13th Dr Leys commenced practice in Ellon as far back as the year 1853 and was for many years one of the [illegible] practitioners in the district He was for several years a member of the Ellon town council and a [illegible] of the peace Dr Leys studied medicine at King's College, Aberdeen and graduated M D there in 1857 He [illegible] in the district but for the last 17 years had been living in retirement having attained an [illegible]

THE CHADWICK LECTURES ON WAR AND DISEASE

THE first of a series of three Chadwick lectures on War and Disease was delivered in the lecture hall of the Royal Society of Arts on Jan 15th by Colonel F M SANDWITH, M D The chair was occupied by Sir WILLIAM COLLINS K C V O, the chairman of the Chadwick Trust

SIR WILLIAM COLLINS said the trustees had been so encouraged by the new departure made two years ago in giving these public lectures that it was proposed to continue in the same lines Under authority conferred by the Trust a prize of £50 and the Chadwick gold medal was offered to the medical officer of the navy and to the medical officer of the army who most distinguished themselves in promoting the health of the sailors and soldiers The Directors General of the Navy and of the Army Medical Departments had given their cordial approval and support, and nominations had been received by the trustees It was hoped that the awards would shortly be announced The period which Dr Sandwith would deal with in this lecture was the century of Chadwick, for he was born in 1800 and died in 1890 It was also the century of Florence Nightingale who died in 1910 That lady was a great friend of Chadwick and the two were closely associated in military and sanitary reform It was Chadwick who introduced Miss Nightingale to John Stuart Mill and to Kinglake. The work of Florence Nightingale in connexion with the military aspect of sanitary reform was beyond all praise, and she showed how informed gentleness and humane efficiency could produce results which previously had been unthought of Yet when attacking incompetence and inefficiency in high places she could be very caustic

Dr SANDWITH devoted this lecture to a consideration of continental wars of the nineteenth century He said there was a general conviction that the success in this present great struggle must lie with those whose spirit endured, whose faith in themselves and their cause never wavered, and that the destiny of nations lay in the spirit and moral of the troops But the medical officer realised that the sternest determination and the most inflexible courage were, to a considerable extent, dependent upon physical conditions Pain, hunger, cold, and sickness lowered the vitality and tended to reduce physical and moral endurance and these complications might do more mischief than the enemy's bullets But our army was now better fitted equipped, and instructed for a prolonged struggle than in any previous campaign In only one previous instance had sanitary science fitted the soldier for his task—namely in the Russo-Japanese War of 1904-5 In recent wars fought on land, of each 100 deaths 20 were from wounds, 80 from disease, the Russo-Turkish war of 1877-8 showed this proportion In the American Civil War there were 3 deaths from disease to 1 from wounds In the French expedition to Madagascar in 1895 there were 29 killed in action, while 7000 died from disease In the United States army during the Spanish American War 14 died from disease to every 1 killed in action The British losses from disease in the South African War were terrible On the outbreak of hostilities with Russia the Japanese were prepared for all eventualities and by attention to the smallest details they were able to show a proportion of 1 dead from disease to 4 dead from wounds Their aim had been to adapt the best hygienic principles to the life of the soldier in times of peace as well as in those of war Hygiene was but little considered until the public awoke to the necessity of enacting certain laws for the preservation of health in the great cities The outbreak of epidemics in these cities frightened local authorities into inquiries as to their cause and led to the appointment of the first Sanitary Commission of which Chadwick was a distinguished member and though he retired from official life in 1854 his hygienic zeal never abated, and when at this time the Crimean War was in full swing he inquired into the sanitary conditions of our army for it was suffering from extreme and to some extent preventable privations in the Crimea The British public were aroused to a realisation of these by the letters of William Howard Russell the great war correspondent, to the *Times* Even in the time of Napoleon's wars the care of the lessened quantity under such conditions The different effect that mode of death exerts upon the adrenalin where the essential cause, cerebral hæmorrhage, was the same, was strikingly seen in two cases In one case death followed 11 hours after a severe and extensive positive hæmorrhage, adrenalin content much diminished, 1 2 mg Evidence here shows drain on glands due to vasomotor medullary action being induced by the sudden rise of blood pressure demanding slower pulse rate In a second case, however, where pachymeningitis hæmorrhagica occurred with two days' coma preceding death, the adrenalin content was 3 0 mg Here the coma deleted any distressing conditions liable to induce gland exhaustion Many facts in this valuable paper throw light also upon cortical function, theories are critically examined, and an account of the technique for reliable gland examination mentioned We have here noted only one, but an interesting part of this subject

POST-LITIGATION RESULTS IN THE TRAUMATIC NEUROSES

AT last year's annual meeting of the American Neurological Association[1] held at Albany, New York, a profitable discussion on post-litigation results in cases of traumatic hysteria and traumatic neurasthenia was initiated by Dr F X Dercum (Philadelphia) who based his paper on some 605 traumatic litigation cases personally examined and recorded for prosecution or defence In 126 of these the injuries were physical In the others, constituting much the larger proportion, the symptoms were those of so called traumatic neurosis, and in many instances Dr Dercum considered them unreal and unessential He took the view that hysteria, for instance, was an innate affection pre existing in the individual suffering from trauma, and his experience was that in such cases the symptoms always persisted until the final settlement of the action, then they subsided and disappeared He gave brief reports of some 20 cases carried into the court room on stretchers or chairs, or "too seriously injured to be brought into court", in all of these the symptoms rapidly vanished after settlement Dr Dercum said the whole subject was of paramount importance to the community, as on it the eventual cost falls He gave it as his opinion that the law should ensure compensation for physical injuries only In the State of Pennsylvania damages for fright were no longer allowed, and he thought that compensation for traumatic hysteria should also, and logically, be excluded Dr Hugh Patrick (Chicago) said he considered that the employers' liability laws were adding to the invalid list enormously, continuously, and increasingly He referred to the state of affairs in Germany and Austria, where, as is well known to neurologists, the burden of the disabled and quasi disabled weighs ever more heavily on the nation In fact, a new neurosis, distinguished as a "fight for compensation neurosis," has been described by German writers Dr Adolf Meyer (Baltimore) pointed out the essential unfairness of restricting compensation to cases of physical injury only Serious shock was surely physical in quality If too hard and fast a line were drawn, there would be a reaction on the part of the legislature, and what he called "emotional jury verdicts' would result He entered a plea for the elimination of protracted litigation, and urged the necessity of all expert professional reports being committed to writing, so that certain types of so called experts could be pilloried and eliminated. Subsequent speakers also considered that Dr Dercum s position was too extreme, and quoted cases where recovery had not followed settlement Dr Pearce Bailey (New York) said that it was urgently desirable to interview the injured immediately after the accident, if no period elapses for the "working up of revengeful feeling" the traumatic neurosis will rarely develop Dr Diller's attitude was on the whole one which we think will commend itself to the physician He alluded to the handicap felt by the physician in treating such patients pending litigation, and gave it as his experience that a gradual improvement takes place after the award of damages, an improvement much more marked than before settlement He held that if an individual in good health is injured in an accident and thereafter suffers from neurasthenic or hysterical symptoms these should be fairly attributed to the accident, they are real and not imaginary, though they might be exaggerated Exaggeration is a common tendency in all kinds of sickness While it is perfectly true that many of the traumatic neuroses would never have occurred had the individual not possessed a neurotic temperament, on the other hand such an individual might have gone on through life without showing marked nervous symptoms had it not been for the accident Apparently little reference was made in the discussion to the great practical importance of the manner in which the claim is settled Large statistics from railway compensation cases in Germany[2] have shown conclusively that the results are much better when compensation is paid in a round sum than when it is awarded to be paid weekly for an indefinite period. Wherever practicable the medical profession should take up a strong position on this point It is apparent, we think, that the matter is too complex to be settled offhand by any radical declaration Neither the employer nor the employee is responsible for the neurotic temperament of the latter, and were the sufferer from traumatic neurosis to be considered devoid of all claim for compensation it would look, as one of the American speakers said, as though he were being penalised for his own nervous instability The subject is of everyday importance and it might be well on some future occasion to obtain a consensus of opinion from the experts o the profession in this country from which to derive some general rules for the guidance of those who are medically concerned with such cases

MYIASIS OF THE URINARY PASSAGES

MYIASIS of the urinary passages is a very rar condition In 1909 Rene Chevrel analysed all th reported cases, of which he could find only 2 He regarded 6 as authentic, 10 as probable, and as doubtful, and he added a case under his ow observation In the *Journal of the America Medical Association* of Dec 26th, 1914, Dr E King has reported the following case A ma aged 32 years, who had been suffering from chron posterior urethritis for some months, on Oct 29t 1914, brought an object which he said he h passed in the urine This was later identified Dr L O Howard, entomologist of the Unit States Department of Agriculture, as the lar disease in childhood and possibly again in later life It is not at present possible to affirm or deny the truth of the theory that natives serve as the reservoir of the virus The Commissioners are satisfied that of the cases which have been recently diagnosed at Lagos and elsewhere as yellow fever a certain number were true examples of that disease It is thought very probable that the malady which prevailed in West Africa in 1910-11 and in 1912 was genuine yellow fever The general measures for the reduction of stegomyia in the towns of the West African colonies appear to be defective, and this matter requires immediate attention by all concerned

[1] Journal of Nervous and Mental Disease December 1914 p 785

[2] THE LANCET Oct 4th 1913 p 1005.

Second Report

The second report contains a retrospect (1) of yellow fever in West Africa as a whole, (2) of fevers on the ships of the British navy on the West African station, and (3) of yellow fever in the colonies, both British and foreign, on the West Coast of Africa. Some account is also given of the then existing health conditions in the West African colonies during 1862 a year marked by exceptional prevalence of yellow fever An analysis is furnished of the epidemics of 1910-11 and 1912 Other subjects, such as racial immunity, clinical types of the disease, and its incidence in childhood, are likewise discussed In setting out their general conclusions the Commissioners say that there is no evidence to show that the infection in each yellow fever outbreak under review had been introduced from outside Africa The mild nature of the attack in certain cases makes the identification a matter of difficulty It is therefore essential that in future all cases of fever should be carefully observed and classified in order that, as far as possible such mild attacks of yellow fever may not pass unrecognised The attention of all workers at this subject should be directed specially to the discovery of a clinical test for the disease

The Commissioners do not underestimate the importance of the researches which are being prosecuted in connexion with the nature of the yellow fever virus, and also those concerning appearances by which its presence could be recognised in the body of the stegomyia mosquito The possibility is admitted that by such researches the desired clinical test may be found, but the extreme practical importance of being able to determine whether a mild case of fever is or is not yellow fever renders it essential that all possible methods should continue to be employed in the clinical study of the malady The opinion is expressed that the day has gone by for endeavouring by the use of euphemistic terms to conceal the presence of yellow fever, and that the only hope of eradicating the disease lies in boldly facing the facts Failure to take all possible steps to destroy a focus of yellow fever is regarded by the Commissioners as an offence against the comity of nations With regard to the very important etiological researches on the nature of the yellow fever virus carried out at Lagos by Dr Macfie and Dr Johnston, of which mention was made in the first report the Commissioners reserve their opinion until the issue of their third report, by which time they will have completed the examination of the microscopical and other material which they have received and which illustrate the appearances presented by the "Seidelin bodies" (paraplasma flavigenum) and their possible connexion with the virus of yellow fever The third report of the Commission should prove very interesting reading

---

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH

City of Liverpool.—As usual Dr F W Hope's annual report gives in clear and attractive form a picture of the [illegible] of work undertaken by the medical officer of [illegible] in a great city We can only select a few matters of interest practically at random from the [illegible] who have been familiar with the incidence [illegible] in Liverpool in years not long past will be [illegible] diagrams which are given as to the recent [illegible] The recurring autumnal ep[illegible] [illegible] of cases in the central [illegible] synchronously with the during [illegible] autumnal [illegible] rise fails altogether to occur in this area For the city as a whole, imported cases, and cases attributed to infection by shell fish together form a proportion of the total of notified enteric fever cases, which is larger year by year, in 1913 as many as 43 per cent of the cases are thus accounted for in the report In that year cockles rather than mussels appear to have been the principal source of infection, the shell fish were consumed raw or else merely steamed or immersed in hot water till the shells opened The new measures adopted for treating tuberculosis and recent developments under the National Insurance Act respecting this disease naturally call for much attention in the report As regards pulmonary tuberculosis, 128 cases were admitted during 1913 to the Fazakerley Sanatorium and 423 to the Park Hill Hospital, which in March of that year was taken over and adapted for the treatment of this disease Practically all the cases admitted were either insured or dependents of insured Three "tuberculosis institutes" have been established in Liverpool, to correspond with the "anti-tuberculous dispensaries" mentioned in the Astor Report of 1912 Cases are sent to these institutes by medical men or by the public health or education authorities, comparatively few direct applications from the patients themselves have so far been received. In connexion with the work among children, assistance is given by the Liverpool Invalid Children's Association, particularly in regard to the preparation of the application forms needed if dependents of insured persons are to be admitted into the various homes or institutions available for tuberculosis in children The completed scheme now coming into operation will as far as possible treat all cases alike, irrespective of their insurance A considerable amount of domiciliary treatment is given, and Dr Hope considers that this needs to be put on a more satisfactory footing, so that the patient, by giving a better recognition of the doctor's directions and the doctor by the display of a little more interest in the subject, can unite to "improve the status of official domiciliary treatment' It may be noted that in Liverpool the district sanitary inspectors are fully utilised in the home visiting of notified cases of tuberculosis, where the practitioner agrees to this course being followed Dr Hope states that so far as Liverpool is concerned there is no reason to think that the additional amount of attention paid to the treatment of tuberculosis has interfered with the far more valuable and important measures of prevention The demolition of unhealthy courts and dwellings and their replacement by healthy houses which has been undertaken for so many years still continues, a diagram of the "St Anne-street Area" before and after its reconstruction is a good object lesson of the thoroughness of the work Formerly the corporation on account of the cost usually did not buy the public houses included in areas scheduled for demolition, this policy however, has now been abandoned, and Dr Hope highly commends the change (We would, however like to see the experiment tried of substituting good working class restaurants at which beer could be obtained with meals) New by laws have been introduced to regulate houses let in lodgings, which give additional powers for dealing with the offences created by not cleansing room floors stairs, and passages and the non-separation of sexes The tenant is now amenable in addition to the lodger As regards smoke abatement, great improvement has been effected in recent years by the reconstruction of the furnaces in many factories and the installation of superior appliances for automatic stoking A new duty has fallen on inspectors from the many complaints of the noise and smell from internal combustion engines and advice has been given by them on the methods to counteract these nuisances by deodorants and silencers Public lectures on smoke prevention have been given under the auspices of the University to persons in charge of furnaces with very satisfactory results The report contains several useful illustrations, though we have some doubt of the moral intended to be drawn from the series of family groups whose photographs appear in the volume

Metropolitan Borough of Islington—Mr A. F Harris reports the registration of 24 deaths from appendicitis during the year of which 12 occurred below the age of 20 and 7 below the age of 10 It is noteworthy that the number of deaths registered from this cause has remained at about 24 year by year since 1904 There were 19 cases of poliomyelitis notified practically no connexion was established between them and the houses affected were all in sick and wounded was lamentably neglected, although there were some distinguished surgeons on his staff In 1854 the Army Medical Department consisted of the Director General an assistant, and about six clerks The head of the department struggled in vain, on the outbreak of the war to create every detail of supply, but on grossly insufficient funds and he had no trained staff It was small wonder that many diseases decimated the fighting line In January, 1855, there were 23,076 sick in the ranks At this time Sidney Herbert was appointed Secretary of War He was a man of fearless and independent character, and with the coöperation of Florence Nightingale he got a staff of nurses at the front, and drastic reforms were introduced in the spring of 1855, a Commission was sent from home and they caused important sanitary works to be carried on, including the construction of hospitals and the improvement of the water-supply The death rate, which in February, 1855, had reached 42 per cent., began to fall, and in June it was only just over 2 per cent A Royal Commission appointed in 1857 to inquire into the medical administration of the army revealed that not only was the mortality due to disease in war time enormous, but that of the army in peace time was double that among the civilian population The high figures in barracks were due to their grossly insanitary condition In the sleeping arrangements only 23 inches of space per man was allowed and the beds were practically touching each other Sometimes four men slept in each bed In spite of many representations, comparatively little change occurred until the Crimean War had drawn public attention to the facts Next, the health of our troops in India received attention Florence Nightingale stated that 60 per 1000 of our troops perished annually in India and preventable disease among them cost the nation £388,000 in a year It was thought that the high mortality there was inevitable and was due to climatic conditions and it was the custom to bleed men on the voyage out, under the idea that "blood freshly made would be of a quality germane to the new climate" In 1860 the first army medical school was founded at Chatham to meet this increasing experience It was subsequently removed to Netley Its first professor was Dr Edwin Parkes, who had written brilliant monographs on dysentery and cholera in India, and whose "Manual of Practical Hygiene" long remained the standard work on the subject Parkes was continually endeavouring to improve the physique and conditions of the soldiers, for at the date he wrote officers and men were clothed in a manner which was calculated to hinder the free movements of the body It was a wonder that such long marches as stood to the credit of some regiments—i e, 42 miles in 20 hours and 62 miles in 26 hours—could be carried out, especially as the soldier had to carry equipment weighing 55 lb Fifty years ago, moreover, the British Army was said to be the most intemperate in Europe. The men had a regular ration of rum served out to them, and in the West Indies men had cheap rum in abundance, and it was often contaminated with lead This did not allay thirst but aggravated it In 1864 Sir Hugh Rose reduced the spirit ration to one-half In the American Civil War men who could not be paid owing to lack of funds, so that they could not buy spirits, were healthier and more cheerful than those who bought alcohol Intemperance in our army had now largely disappeared, and Dr Sandwith commended the wisdom of the Czar in prohibiting the sale of vodka throughout his dominions during this crisis and expressed the wish that the magistrates of our great cities might be given greater powers in that direction Alcohol administered in small quantities after a fatiguing march acted as an appetiser when men did not feel inclined for food, and abstainers under normal circumstances were glad of this aid Alcoholic excess was partly responsible for the devilish performances of German officers and soldiers with unprotected women He concluded by paying a high tribute to the organisers in the present war

ROYAL COLLEGE OF SURGEONS OF ENGLAND

MEETING OF COUNCIL

A QUARTERLY meeting of the Council was held Jan 14th, SIR W WATSON CHEYNE the President being in the chair

The Secretary reported the death on Dec. 31st last of Mr Thomas Bryant, past President, and past member of the Council and of the Court of Examiners of the College A vote of condolence was passed expressing the appreciat of the Council of Mr Bryant as President and in othe capacities

Leave of absence was given to the Conservator of the Museum for the purpose of going to America to deliver a course of five lectures on anthropology at the Western Reserve University, Cleveland, Ohio

A vote of thanks was given to Mr G Buckston Browne for a collection of lithotrites presented by him to the Museum and a vote of thanks was given to Sir John Tweedy for his interesting and valuable gifts to the library

It was resolved to contribute a sum of 50 guineas from the funds of the College to the Belgian Doctors' and Pharmacists' Relief Fund

SIR W WATSON CHEYNE was reappointed a member of the Court of Governors of the University of Birmingham for three years

The PRESIDENT reported the delivery by Sir Frederic Eve on Dec. 15th of the Bradshaw Lecture on Acute Hæmorrhagic Pancreatitis, with Remarks on the Etiology of Chronic Pancreatitis The best thanks of the Council were given to Sir Frederic Eve for his lecture, and he was requested to publish it

The PRESIDENT stated that the vacancy on the Court of Examiners occasioned by the termination of office by Mr Bilton Pollard would be filled at the ordinary meeting of the Council on Feb 11th.

REPORTS OF THE YELLOW FEVER COMMISSION (WEST AFRICA)

THIS Yellow Fever Commission, as our readers may remember was appointed in January, 1913, by the Secretary of State for the Colonies with the object of studying the nature and frequency of the fevers occurring among Europeans, natives, and others in West Africa, especially with regard to yellow fever[1] The members of the Commission are four in number—namely, Sir James Kingston Fowler, Colonel Sir William B Leishman, Sir Ronald Ross, and Professor W J R Simpson They have now issued two reports giving a general account of the steps taken to acquire information and the results so far obtained

First Report

The first report, dated Oct 7th, 1913, is signed by the three first of the above named members of the Commission, Professor Simpson having been absent in East Africa advising the authorities there on health matters A brief review is given of the circumstances which led up to the appointment of the Commission and the measures taken to organise and prosecute the investigation Copies of the forms drawn up and sent out to the West African Medical Staff and to other medical practitioners in the various colonies are appended In these information was asked for and coöperation in the inquiry invited Several officers possessing special training and qualifications were appointed to carry out work for the Commission at different centres in West Africa, and one member of the West African Medical Staff, Mr J M O Brien, on his own initiative, in order to increase his knowledge and experience of the disease spent his leave in Guayaquil, in the South American State of Ecuador This town possesses an evil reputation as regards yellow fever which is endemic there and often assumes epidemic proportions Guayaquil it may be added, is notorious all over the Pacific as one of the chief diffusing centres of the disease in South America. The Commissioners state that already certain scientific observations have been made at Lagos which if confirmed promise to prove of great importance in relation to the etiology of the malady and in consequence Dr Harald Seidelin, the well known yellow fever expert was despatched to Lagos to examine the results obtained and to confer with the two local investigators, Dr J W Scott Macfie and Dr J E L Johnston

At present the Commissioners are not in a position to make any statement concerning the Lagos observations until they are supported by further evidence The views previously put forward by the late Sir Rubert Boyce are discussed concerning the alleged immunity against yellow fever possessed by natives and acquired through attacks of the one from small pox The mean annual death rate from hese diseases was equal to 2·0 against 1 3 per 1000 in he large English towns The deaths attributed to whooping cough which had been 28, 44, and 55 in the three preceding weeks were 56 last week and included 30 in Glasgow, 11 in Dundee 5 in Aberdeen and 4 in Clydebank The deaths referred to diphtheria, which had been 16, 14, and 21 in the three preceding weeks fell to 10 last week, of which 4 were registered in Edinburgh and 2 in Aberdeen The fatal cases of scarlet fever, which had been 15 17, and 13 in the three preceding weeks further fell to 9 last week, and comprised 6 in Glasgow and 3 in Aberdeen The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 12, 11, and 17 in the three preceding weeks, fell to 7 last week, of which 4 belonged to Glasgow The deaths referred to measles, which had been 5, 10, and 7 in the three preceding weeks, were again 7 last week and comprised 6 in Dundee and 1 in Glasgow The 3 fatal cases of enteric fever occurred in Glasgow, and were slightly in excess of the average in recent weeks

---

[1] THE LANCET April 25th 1914 p 117

The deaths referred to diseases of the respiratory system, which had steadily increased from 154 to 265 in the five preceding weeks further rose to 275 in the week under notice 35 deaths resulted from different forms of violence, against 42 and 32 in the two preceding weeks

HEALTH OF IRISH TOWNS

In the 27 town districts of Ireland with an aggregate population estimated at 1,212,380 persons at the middle of this year 693 births and 568 deaths were registered during the week ended Saturday, Jan 16th The annual rate of mortality in these towns, which had been 17·0, 27 8 and 25·5 per 1000 in the three preceding weeks, further declined to 24·4 per 1000 in the week under notice During the 13 weeks of last quarter the mean annual death rate in these towns averaged 18 8 against 14 9 and 16 8 per 1000 in the English and Scotch towns respectively The annual death rate last week was equal to 29 2 in Dublin (against 19 6 in London and 24 2 in Glasgow), 21 7 in Belfast 29 9 in Cork 27 8 in Londonderry 17 6 in Limerick, and 30·4 in Waterford while in the 21 smaller towns the mean death rate did not exceed 18 3 per 1000

The 568 deaths from all causes were 47 fewer than in the previous week, and included 48 which were referred to the principal epidemic diseases, against 42 and 38 in the two preceding weeks Of these 48 deaths, 14 resulted from infantile diarrhœal diseases 12 from measles 10 from whooping-cough 8 from scarlet fever 3 from diphtheria and 1 from enteric fever, but not one from small pox. The mean annual death rate from these diseases was equal to 2 1, against 1 3 and 2·0 per 1000 in the English and Scotch towns respectively The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 9 10 and 11 in the three preceding weeks further rose to 14 last week, and included 7 in Dublin and 2 in Belfast The deaths referred to measles, which had been 9 9 and 6 in the three preceding weeks rose to 12 last week and comprised 10 in Belfast and 2 in Cork The fatal cases of whooping-cough which had increased from 3 to 11 in the five preceding weeks were 10 last week of which 5 belonged to Belfast and 3 to Dublin The deaths attributed to scarlet fever, which had been 3 9 and 12 in the three preceding weeks rose to 8 last week and comprised 5 in Belfast 2 in Cork and 1 in Waterford The deaths referred to diphtheria were recorded in Belfast Cork and Portadown and the fatal case of enteric fever in Dublin

The deaths referred to diseases of the respiratory system, which had been 95 162 and 139 in the three preceding weeks rose to 164 in the week under notice Of the 568 deaths from all causes 140 or 25 per cent occurred in public institutions and 8 resulted from different forms of violence The causes of 25 or 4·4 per cent, of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest in the English

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

THE following appointments have been made —Fleet-Surgeon H. L Penny to the *Vivid*, additional for disposal Staff-Surgeon T E Blunt to the *Pembroke* additional, for disposal Surgeon G F B Page to the *Vivid*, additional for disposal, and W A S Duck, A Fairley, and L Moss to the *Victory*, additional for disposal Temporary Surgeons J A Gordon, P A. Lemass J F McQueen and G L Ritchie to the *Victory* additional, F T Fisher to the *Pembroke*, additional, for disposal, and E M Lauderdale to the *Victory*, additional, for Haslar Hospital

James Grimoldby has been granted a temporary commission as Surgeon in His Majesty's Fleet

ROYAL NAVAL VOLUNTEER RESERVE

Temporary Commissions in the Royal Naval Volunteer Reserve have been issued as under —Lieutenants Ambrose Congreve Redmond Walter McGrath Surgeon Frederick William Willway

Surgeon Probationer J C Sinclair to the *Woolwich*, for the *Badger*, vice S R Prall (resigned)

ARMY MEDICAL SERVICE

Brevet Colonel William H. Horrocks is appointed an Honorary Surgeon to the King vice Surgeon Major General Sir J B C Reade K C B (dated Nov 6th 1914)

Colonel Thomas J O Donnell, D S O , is retained on the active list under the provisions of Article 120, Royal Warrant for Pay and Promotion, and to be supernumerary (dated Jan 18th)

ROYAL ARMY MEDICAL CORPS

Supernumerary Captain Wilfred W Treves is restored to the establishment (dated Jan 14th)

Supernumerary Captain John Gilmour is restored to the establishment (dated Jan 7th)

Lieutenant Robert William Walter Vaughan relinquishes his temporary commission (dated Dec 31st, 1914)

Lieutenant William H Johnston resigns his commission (dated Jan 16th)

Lieutenant John Spencer Daniell relinquishes his temporary commission (dated Jan 19th)

The undermentioned to be temporary Captains —Gordon Morgan Holmes (dated Nov 5th 1914) Claude Gouldesbrough (dated Dec. 28th, 1914) and James Ewing (dated Jan 5th)

Temporary Lieutenant Thomas Renton Elliott to be temporary Captain (dated Jan 14th)

The undermentioned to be temporary Captains whilst serving with the Red Cross Hospital, Netley —Dated Jan 19th. Donovan Blaise Pascall and Walter Gibson Marsden

The undermentioned to be temporary Lieutenants —Dated Nov 2nd 1914 Francis Hubert Storey Dated Dec 15th, 1914 Archibald Hector Maccoll Robertson Dated Dec 16th 1914 Charles Cavanagh Dated Dec 17th 1914 George William Fleming Dated Dec 18th, 1914 Donald Campbell Dated Dec 20th, 1914 Alfred George Caldwell Dated Dec 21st, 1914 Robert John Jones Albert Edmund Samuel Martin Charles Sand, Herbert Harland Raw George Llewellyn Brunton, and Roland Henry Fletcher Dated Dec 22nd 1914 Francis De Sales McMenamin Dated Dec 23rd 1914 Leslie Charles Johnston George Mitchell Archibald Langwill Alfred Squire Taylor, and Lacey Bathurst Dated Dec 24th, 1914 John Warwick Dated Dec 25th 1914 Jerome Ivo O Sullivan Michael Sullivan, Robert Archibald Slater Sunderland, Mortimer Hynes Norman Garfield Thornley James Sackville Martin Robert McLeod Veitch Edward Mansfield, John Hannay Douglas Martin Melvin Cruickshank, David Cochrane Hanson William De Malet Peyton, Harrold John Pickering David Haig Alan Everley Taylor Edgar Coningsby Myott Harry Stanger Sylvester Davidson Fairweather Hugh Faulkner Henry William Turner Peter

streets lying off main lines of traffic No secondary case *occurred in any household* Mr Harris's practice is to disinfect the rooms and bedding in every case, the latter being adopted more for the purpose of bringing the infectious nature of the disease before the minds of the people than because it is considered strictly necessary In the present state of uncertainty as to the *conditions* under which poliomyelitis is spread, such precautions are considered *desirable*, though their empirical nature is admitted The prompt notification and isolation of diphtheria cases in Islington during the year appears to have had a distinct result in limiting the spread of the disease, the 550 cases notified came from 473 houses, in only 34 of these were there *two cases in the house* and in only 12 houses were there three cases or more In as many as 427 houses only one case was known Mr Harris alludes to a consideration often lost sight of by those who complain of the cost of hospital isolation of infectious diseases in children The educational authority will not permit any children to attend school from infected houses, and in the absence of *isolation many scholars would have to be absent* from school six weeks or more, with the result in loss of education and *dislocation* of the educational machinery, which would entail a considerable cost, what the ratepayers lose in one direction they gain, or nearly so, in another The Islington series of reports have always some valuable observations on food inspection and adulteration, and the 1913 *report is no exception to the rule* Medical officers who are interested in the history and prevalence of adulteration will find much information in Mr Harris's chapter on this subject Generally speaking, the efforts made in this borough appear to be effective in getting food adulteration detected and punished, so far as the limited provisions of the present law allow In particular, Mr Harris is satisfied that *farmers' milk coming straight to* London, on Sundays as well as weekdays, is maintained at high quality, and his results should be gratifying to farmers "who are frequently made the scapegoats of interested persons" The least satisfactory feature of the analyst's reports is the frequency of the fraud of substituting margarine for butter The machinery for detecting the fraud exists *and is skilfully used, but the fraud itself* is so profitable that the fines inflicted seem to fail to put a stop to it

VITAL STATISTICS

VITAL STATISTICS FOR 1914

THE following statement shows the birth and death rates and the rates of *infantile mortality* in England and Wales and in certain parts of the country during the year 1914, the figures being provisional —

—	Annual rate per 1000 living			Deaths under one year to 1000 births
	Births	Deaths		
		Crude	Standardised *	
England and Wales	23·6	13·9	13·6	105
97 great towns including London	24·9	14·6	14·9	113
145 smaller towns	23·6	12·8	12·9	104
England and Wales less the 242 towns	21·9	13·3	12·2	93
London	24·6	14·4	14·4	103

* The standardised death rates are the rates which would have been recorded had the sex and age constitution of the populations *of the* several areas been identical with that of England and Wales as enumerated in 1901 A description of the method of standardising these death rates is to be found in the Registrar-General's Annual *Report* for 1911 p xxix

HEALTH OF ENGLISH TOWNS

In the 96 English and Welsh towns with populations *exceeding 50 000 persons* at the last census 8897 births and 6545 deaths were registered during the week ended Saturday, Jan 16th The annual rate of mortality in these town which had been 14·0, 21·3 and 19·4 per 1000 in the thr preceding weeks further fell to 18·8 per 1000 in the week under notice During the 13 weeks of last quarter th mean annual death rate in these towns averaged 1 against a corresponding rate of 15·3 per 1000 in Lon The annual death rate last week ranged from 7·2 i *Gloucester, 11·2 in* Tottenham, *12·9 in* Rhondda, 13·0 in Smethwick, and 13·2 in Northampton, to 25·1 in Linco *25·2 in* Ipswich *26·0 in Blackpool, 26·3* in Gillingham a 28·8 in Merthyr Tydfil

The 6545 deaths from all causes were 191 fewer than th number in the previous week, and included 454 which were referred to the principal epidemic diseases, against 5 and 487 in the two preceding weeks Of these 454 deaths 195 resulted from measles, 76 from whooping-cough, 7 from infantile diarrhœal diseases, 63 from diphtheria, 4 from scarlet fever, and 11 from enteric fever, but n one from small pox The mean annual death rate from these diseases was equal to 1·3, or 0·1 per *1000* less th in the previous week The deaths attributed to measles *which had been 175, 269, and 183 in the three* preceding weeks, rose to 195 last week and caused th highest *annual death rates of 2·1 in* Newcastle-on-Tyne 2·3 in Wigan, 2·5 in Plymouth, 2·6 in Enfield and in *Darlington, 3·1 in St Helens, 3·3 in Huddersfield* 4·5 in Grimsby, and 6·7 in Merthyr Tydfil The deaths *referred to whooping-cough, which had steadily increased* from 35 to 93 in the eight preceding weeks, fell to 76 last *week, and included 13 in London, 6 in Leeds,* 5 in Sunderland, 4 each in Willesden Bristol, and Liverpool and 3 in *Newcastle on Tyne* The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 70, 85, and 84 in the three preceding weeks further fell to 75 last week of which 20 were registered in London, 6 each in Birmingham *ham and Manchester, and* 4 in Bristol The deaths attributed to diphtheria, which had been 66, 89, and 77 *in the three preceding weeks* further fell to 63 last week, and included 15 in London, 5 in Liverpool, and 3 each in Birmingham *ham and Manchester* The deaths referred to scarlet fever which had been 30, 31, and 35 in the three preceding weeks were 34 last week, of which 10 occurred in London, 3 in Sheffield, and 2 each in Manchester and Preston The *fatal cases of enteric fever*, which had been 12, 20, and 15 in the three preceding weeks, further declined to 11 last week and included 2 in Portsmouth

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had declined from 5055 to 4153 in the seven preceding weeks, had further fallen to 3952 on Saturday last, 338 new cases were *admitted* during the week, against 348, 436 and 321 in the three preceding weeks These hospitals *also* contained on Saturday last 1641 cases of diphtheria, 82 of measles 61 of enteric fever and 34 of whooping-cough, *but* not one of small pox. The 1702 deaths from all causes in London were 36 less than in the previous week, and corresponded to an annual death rate of 19·6 per 1000 The deaths referred to diseases of the respiratory system, which had been 270, 562, and 497 in the three preceding weeks further fell to 477 in the week under notice, but were 72 in excess of the number in the corresponding week of last year

Of the 6545 deaths from all causes in the 96 towns, 211 resulted from different forms of violence and 463 were the subject of coroners' *inquests*, while 1742 occurred in public institutions The causes of 64, or 1·0 per *cent.* of the total deaths, were not certified either by a registered medical practitioner or by a coroner after inquest All the causes of death were duly *certified* in Sheffield, Leeds Bristol West Ham Hull, Newcastle-on Tyne and in 66 *other* smaller *towns* *Of the 64* uncertified causes 13 were registered in Liverpool, 12 in Birmingham, 5 in Gateshead, and 3 in *London*

HEALTH OF SCOTCH TOWNS

In the 16 largest Scotch towns with an aggregate population estimated *at 2 344,400 persons* at the middle of this yea 1123 births and 1027 deaths were registered during *the week* ended Saturday, *Jan* 16th The annual rate of mortality in these towns, which had steadily increased *from* 17·7 to 24·5 *per 1000 in the five preceding* weeks declined to 22·8 per 1000 in the week under notice During the 13 weeks of las quarter *the* mean annual death rate in these towns averaged 16·8, against 14·9 per 1000 in the large English towns *The* annual death rate last week ranged from 14·1 in Kilmarnock 14·9 in Leith and 15·1 *in* Motherwell, to 27 in Greenock, 28·2 in Dundee and 29·5 in Ayr

The 1027 deaths from all causes were 73 fewer than in the previous week, and included 92 which were referred to the principal epidemic diseases, against numbers increasing from 77 to 117 in the three preceding weeks. O these 92 deaths, 56 resulted *from* whooping-cough 10 from infantile diarrhœal diseases, 7 from measles, 9 from scarlet fever, 7 from diphtheria and 3 from enteric fever, bu no

THE PRESS AND ANTITYPHOID INOCULATION

To the Editor of THE LANCET

SIR,—I notice in this evening's issue of the *Evening Standard* a full page advertisement (p 13) on behalf of the "British Union for the Abolition of Vivisection." The antivivisectionists can be ignored on account of their stupidity, but this particular advertisement deserves the most severe censure in that it is anti recruiting

The only way to deal with such a paper is on their own lines—commercial I hope, therefore, that all medical men, like myself, will in future refuse to buy it

I am, Sir, yours faithfully,

HUNTER TOD

Upper Wimpole-street, W Jan. 16th 1915

ANATOMY AT THE PRIMARY FELLOWSHIP EXAMINATION

To the Editor of THE LANCET

SIR—I have been asked repeatedly by other people than unsuccessful candidates to write to you about the questions being set in the anatomical part of the primary examination for the F R.C S The trouble is that this, which used to be a perfectly straightforward though difficult examination in topographical anatomy, seems now to be tending to become in addition a test of the candidate's knowledge of the more philosophical side of the science I hesitate to add to the troubles which I know surround the examiners for the Primary Fellowship at all times but I think that they may possibly bear with or even welcome the experience of one who has served a ten years' apprenticeship in the post which they now fill. It should be remembered that the primary examination is the point at which most candidates for the keenly sought diploma of Fellow are rejected, and the examiner's chief duty is to do his utmost to prevent men passing until they are well enough grounded in anatomy to be able to make the most of the higher teaching in surgery which they are to receive later

Anatomy has two sides Firstly, a working knowledge of all the parts

questions are to become a feature of this examination candidates will seek the aid either of small text-books, which they will try to learn by heart or of crammers whom they will trust to gauge quickly and skilfully the range of knowledge which each examiner has and the kind of questions he is likely to ask

The average time which a candidate presenting himself for the first time for this examination spends on learning his anatomy and physiology is, I think, from 20 months to two years This is not a bit too long for him to learn his way thoroughly and confidently about the human body But if morphology is expected in addition the technical pilot's knowledge of the body must suffer, and the subject is so vast that it must always be a chance whether a man happens to be able to do justice to a morphological question or not If he has had the question intelligently anticipated for him he, of course, scores heavily, and may thus make up for serious gaps in his knowledge of the real anatomy of man.

My point is that a surgeon should be at home in any part of the human body, and a clever man can just get this knowledge in two years or a little less To ask more is to endanger the acquisition of this real knowledge and to substitute for it, to some extent, an ill digested mass of theory derived from text-books and class notes Perhaps I am unduly hard on the value of the scientific side of anatomy, although it is my hobby, but I am only considering now the education of the young surgeon, and am anxious to remind myself and others that what we examiners ask the students will learn—usually in the easiest and least permanent way A practical knowledge of the body is so essential and so easily detected that I am loth to see candidates given the chance of substituting for it a second hand knowledge of the more interesting though less useful science of morphology

I am, Sir, yours faithfully,

St. Thomas's Hospital, Jan. 13th, 1915. F G PARSONS

THE PHARMACOPŒIAL DOSE

To the Editor of THE LANCET

SIR,—I am instructed on behalf of the pharmacists of Great Britain to solicit your aid in calling the attention of the medical profession to the wording of a portion of the preface to the new British Pharmacopœia In that preface the following statement is made —

Bennett, George B Hadden, Francis J Hallinan, Thomas P Inglis, William M Lansdale, Francis C Lapage, David S Martin, and Thomas Sheedy

TERRITORIAL FORCE

Army Medical Services

Lieutenant-Colonel Conrad T Green, from the Welsh Casualty Clearing Station, to be Assistant Director of Medical Services, Welsh Reserve Division, and to be granted the rank of Colonel (temporary)

Lieutenant-Colonel Harry T Challis, from the 3rd East Anglian Field Ambulance, to be Assistant Director of Medical Services, East Anglian (Reserve) Division, with the temporary rank of Colonel

Yeomanry

Yorkshire Hussars (Alexandra, Princess of Wales's Own) Surgeon Captain Walter Henry Cheetham to be Surgeon Major (temporary)

Royal Army Medical Corps

Surgeon Major Edward Herbert Myddelton Gavey (Retired List, Honourable Artillery Company) to be Major

3rd East Anglian Field Ambulance Captain William I Cowell resigns his commission on account of ill health

2nd Highland Field Ambulance Captain James Forbes MacIntosh to be Major (temporary)

1st West Riding Field Ambulance To be Lieutenants Edwin Samuel George Fowler and Henry Whitteron Robinson

3rd London General Hospital Stanley Herbert Warren to be Captain, whose services will be available on mobilisation To be Lieutenants John Bromley Rawlins and Cecil Rhodes Harrison

3rd Scottish General Hospital Captain Alexander J Archibald, from the 4th Scottish General Hospital, to be Captain

1st London (City of London) Sanitary Company Lieutenant Cresacre G Moore to be Captain (temporary)

2nd London Sanitary Company To be Lieutenants Patrick Albert Galpin, George Gordon Johnstone, George Leslie Eastes, Gerald Quin Lennane, George William Ellis, Walter Key Parbury, John H Wood, and Ernest B Pike

2nd London Casualty Clearing Station To be Captains George Herbert Hunt and Lionel Colledge

2nd North Midland Field Ambulance Lieutenant Horace Guy L Haynes, from Attached to Units other than Medical Units, to be Lieutenant

1st Northumbrian Field Ambulance The undermentioned Lieutenants to be Captains (temporary) Edward B Kitching and Joseph W Craven

2nd Northumbrian Field Ambulance William Craig Stewart to be Lieutenant

1st London (City of London) General Hospital Charles Ernest West to be Captain, whose services will be available on mobilisation

4th Northern General Hospital George Samuel Levis to be Captain, whose services will be available on mobilisation Plomer William Young to be Captain, whose services will be available on mobilisation

3rd Southern General Hospital James Frederick Robinson to be Captain, whose services will be available on mobilisation

South Wales Mounted Brigade Field Ambulance John Ambrose Cooke to be Lieutenant

3rd Home Counties Field Ambulance Henry John Brownrigg and Philip Theodosius Jones to be Lieutenants

1st East Lancashire Field Ambulance Lieutenant Stanley Hodgson, from Attached to Units other than Medical Units, to be Lieutenant

2nd East Lancashire Field Ambulance John James Hummel to be Lieutenant

2nd West Riding Field Ambulance William Herbert Smailes and Digby Wrangham Hardy to be Lieutenant

1st Northern General Hospital Major Frederick C Pybus from the permanent personnel to the list of officers whose services will be available on mobilisation Captain Daniel W Patterson, from the list of officers whose services will be available on mobilisation to the permanent personnel

3rd Northern General Hospital The undermentioned to be Lieutenants Arthur Robertson Wightman and George Ewart Martin

Notts and Derby Mounted Brigade Field Ambulance Frank Standish to be Lieutenant

West Riding Casualty Clearing Station Lieutenant Colonel William McGregor Young from the 2nd West Riding Field Ambulance to be Lieutenant Colonel

The undermentioned to be Lieutenants Charles Marsh Gozney and Arthur Stuart Hebblethwaite

Sanitary Service Albert Henry Bygott to be Captain whose services will be available on mobilisation

Attached to Units other than Medical Units —To be Majors (temporary) Captain Matthew B Ray, Captain Robert Thornton, and Captain Vincent Howard To be Captains (temporary) Lieutenant George C Jeaffreson and Lieutenant Richard V Favell Lieutenant Cecil W Rowntree is seconded To be Lieutenants Hugh Douglas McCrossan Harold Francis Lewis Hugo, and Thomas Rhind

TERRITORIAL FORCE RESERVE

Royal Army Medical Corps

Captain Edward P Minett, from the 6th London Field Ambulance, to be Captain

TEMPORARY COMMISSIONS IN THE ROYAL ARMY MEDICAL CORPS

It is notified by the War Office that there are several vacancies for temporarily commissioned officers in the Royal Army Medical Corps Candidates should be fully qualified medical men, under 40 years of age Applications should be made at once to the Secretary, War Office, Whitehall

OUTFIT ALLOWANCES

By a recent Army Order all officers granted permanent first commissions in the R A M C since August 4th and during hostilities will receive an outfit allowance of £50, to include cost of camp kit Officers granted temporary first commissions will receive £30 and £7 10s for camp kit

DEATHS IN THE SERVICES

Deputy Surgeon General George Alder Watson, I M S, Bengal Army, retired, at the age of 83, at his residence Hendre, Cheltenham, on Jan 12th He entered the Bengal Medical Service in 1855, and during the Indian Mutiny served with the 6th Battalion Bengal Artillery at Mhow in 1857, at the siege of Dhar, and also in the actions near Mundisore and Goorarea (medal and clasp) He served in the Afghan War of 1879 and took part in the advance on Kandahar and Kelat-i Ghilzai (medal) He retired in 1885.

The King has given to Temporary Surgeon James Charles Baggs, R N , late medical officer of health, Monthon Puket, authority to wear the Insignia of the Fourth Class of the Order of the Crown of Siam which has been conferred upon him by His Majesty the King of Siam, in recognition of valuable services rendered

---

THE BEQUESTS OF THE LATE DR I BURNEY YEO —Dr I Burney Yeo, emeritus professor of medicine at King's College, whose death was recently recorded in our columns, left estate valued at £95 413 with net personalty of £94,366 By his will he left £3000 to the Royal Medical Benevolent Fund to found an annuity fund to be known as The Burney Yeo Bequest", £3000 to the Royal Medical Benevolent College, Epsom for a similar purpose, and £5000 to King's College (London) Hospital Medical School for a "Burney Yeo Fund' to be used for furthering the success of the school After making some personal bequests he left the ultimate residue of his estate, one moiety to the Royal Medical Benevolent Fund and the other to the Royal Medical Benevolent College. The work of the Royal Medical Benevolent Fund is regularly recorded in our columns, and our readers know how invaluable it is The medical foundation of Epsom College offers educational and pecuniary advantages of the highest sort to the sons of medical men The generous bequest to the College will materially help towards the £7000 a year which is required for the relief of urgent cases Dr Burney Yeo by his disposition of his fortune has become a great medical benefactor of the medical profession

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY —The usual monthly meeting of the executive committee of this society was held on Jan 15th Dr F J Allan in the chair The reports were considered on members permanently incapacitated of whom there are now 42 receiving annually over £4000 in sickness benefit The society provides practically, an annuity to age 65 of from £1 1s to £3 3s per week for each member so afflicted The year, as a whole has been highly successful About 120 members are serving either at the front or with their regiments at home and in the colonies So far only three claims have been made as a direct result of the war two being from illnesses contracted owing to exposure and overwork and one from a death resulting from wounds Applications are constantly being received from younger members of the profession taking temporary commissions in the Royal Army Medical Corps or serving in the various Red Cross and base hospitals All inquiries in respect of these should be addressed to the secretary Mr Bertram Sutton 300, High Holborn W C shows that the "vertebral" contact of the pancreas is almost as direct as the heart's "sternal" contact, whilst his statement confirms the experience of pathologists that swelling of the gland (sometimes much swelling) is the rule at the early stage The sequel, *qua* localisation, is largely governed by the decubitus, which is inevitably dorsal Any fluid collections, whether cystic, hæmorrhagic, or purulent, inevitably seek the dorsal plane of the thoracic and of the lumbar spinal groove, in close approach to the dorsal surface In that mechanical predicament, if we should have any use for evidence from physical signs, these might more probably be found in the safe exploration of the unconcerned dorsal field than in the danger zone of a tender and badly implicated abdomen, even though, as is sometimes reported, this should not be at first tumefied To that statement there is nothing this letter can add, but to ask, Why should we strain to percuss at a pericardial effusion, happily seldom now fatal, nay, often apt to be a merely ephemeral rheumatic episode? Why percuss the liver for congestion, or cyst, or abscess if the deadly risks of pancreatitis and of its operations are not an urgent appeal for physical signs when available? Granted that British medicine may not be singular in that lofty indifference for the aid of physical examination (where can this be harmlessly applied except at the back?), that safety "in numbers" adds none to the patient He is diagnosed—normally after death, not infrequently by the operation, rarely without it, but it would seem never by any examination for his dorsal physical signs, which keep faith with him to the grave

I am, Sir, yours faithfully,

Upper Brook-street W Jan 8th 1915 WILLIAM EWART

FROST-BITE

To the Editor of THE LANCET

SIR,—In Mr A W Mayo Robson's opportune article on Frost bite in THE LANCET of Jan 16th I note that he does not suggest any internal medication and that for prevention he only urges care of the feet and legs in various ways In view of the analogy, pointed out by himself between mild frost bite and chilblains I would like to ask whether he or any reader of THE LANCET has tried calcium salts for prevention or cure of frost bite Since two days' medication with liquor calcii chloridi, ♏ 60 in all, proves almost a specific for chilblains the fact suggests the possibility of its usefulness, either for prophylaxis or treatment of the graver trouble Moreover calcium favours the coagulation of the blood if wounds are also incurred The lactate would be more convenient under war conditions and is reputed about as efficacious if fresh

I am, Sir, yours faithfully

available to which the war will give rise but the matter is urgent, and the medical department of the army with its civil consulting surgeons will do well to give the matter immediate attention My object, however, is not so much to insist on the importance of a consideration of the general treatment of these serious conditions, but to express my personal opinion as to the undesirability of ever plating or wiring any of these compound fractures In civil practice, with all the facilities which are afforded by well found hospitals, it has gradually come to be recognised by most surgeons that compound fractures should never be wired or plated This opinion has been of only slow growth, for a long time it was felt that, as in a compound fracture the bone was already exposed, the surgeon was more readily justified in applying a plate immediately than in a simple fracture, but the results of this practice have shown that almost invariably compound fractures plated immediately do badly, and sooner or later the plate has to be removed If such unsatisfactory results are almost certain in peace time, how can we expect better results when the operation has to be performed under greater difficulties, and in wounds probably much more septic than commonly found in civil practice, and when, further, a greater length of time has elapsed since the infliction of the injury? Moreover, the need to remove the plate later is only the least of the evils which may follow this method of treatment It may lead to loss of the limb or even loss of life itself. I am writing with no personal knowledge of the work on the other side of the Channel, but I have heard that such attempts have been made, and I feel strongly that these heroic attempts to obtain perfect results may often lead to utter failure and loss of life or limb Will not some of those who have seen wiring and plating of compound fractures in this war tell us definitely what results have been obtained? We shall all receive the information gratefully, and, provided care is taken to make the statistics correct such information must prove of great benefit to us all

I am, Sir, yours faithfully,

Jan 18th 1915 F R C S

"TENDIMUS HUC OMNES"

To the Editor of THE LANCET

SIR,—Under this heading there appeared in THE LANCET of Jan 9th a letter from "A M D" criticising the prevalent impression that the loss of life among soldiers in war time greatly exceeds that which is experienced by non combatants in the civil population Your correspondent quotes a pharmacist to refer back a prescription to the prescriber

If it could be arranged as a *uniform* practice that where a practitioner orders an unusually large dose of any particular potent drug such dose should be initialled by the prescriber, all possibility of ambiguity would thereby be removed

I am, Sir, yours faithfully,
W J UGLOW WOOLCOCK,
Secretary, Pharmaceutical Society of Great Britain.

Bloomsbury-square, W C, Jan 15th 1915

NON - PANEL PRACTITIONERS AND INSURANCE ACT CERTIFICATES

To the Editor of THE LANCET

SIR,—Previous to the passage of the National Insurance Act, and since, I have been a very active and strong opponent of the "medical benefit" clauses of the Act I have always considered it to be, and still hold the same opinion, derogatory to the members of the profession to accept service on the panel on the terms and conditions under which service is rendered During the operation of the Act I have been consulted by large numbers of insured persons, and when necessary have given them certificates of illness as a non panel practitioner, which have always been accepted by the Approved Societies of which they were members, and their so called "sickness benefit" has been paid In consequence of the new scheme embodied in Memorandum 211/I C on the question of "certificates for sickness benefit," whereby all certificates have to be uniform, I, on the suggestion of the National Medical Union, wrote to the clerk of the London Insurance Committee requesting him to send me a supply of the "official certificates" for use in the case of insured persons who may consult me in the future The reply I received is given below

In view of the decision in the case of "Heard *v* Pickthorne" this appears to me an attempt to "bluff" non panel practitioners and to force them to place their names on the panel

I am, Sir, yours faithfully,
London, Jan 13th, 1915 JOHN MACKEITH

[ENCLOSURE]

With reference to your letter of Jan 3rd, 1915, I have to inform you that the Committee are able to supply forms *for medical certificates to practitioners who are on the panel* and also to those practitioners with whom insured persons have been granted permission to make their own arrangements As you are not on the London panel, and further, as no insured person has been allowed to make his own arrangements with you, it is not possible for the Committee to supply you with certificate forms as you request

I am, &c.,
(Signed) THOMAS BATEY,
Clerk of the Committee

To the Editor of THE LANCET

SIR,—The following are two incidents illustrating the latest attempts on the part of the Government to crush such of us as do not approve of the National Insurance Act One of our members has reported to me that an insured patient under his care complained that although her sick money had been paid up to the end of the year it was now being withheld owing to his certificate being of no use because not on the proper form He thereupon wrote to the clerk of the Local Insurance Committee requesting to be supplied with a book of the new forms, but was told that his request could not be entertained as such forms were only issued to panel doctors He has since forwarded the correspondence to the Insurance Commissioners with a request for the redress of this injustice, which seems to me about as hopeful as a complaint from the shepherd to the wolf would be, more particularly seeing that he has since found out that on receipt of his request the clerk wired to the Commissioners for instructions

In a second case of deadlock our member prompted the insured patient to write to the secretary of her approved society pointing out that as she had been regular in her subscriptions she expected them on their part to be prompt in their payments, seeing that she had complied with the law by presenting the certificates of a qualified medical man He wrote on his own account pointing out that the society's action was not only distinctly illegal, but also calculated to damage him, and that failing a retraction and apology within 48 hours he would *take the case into the law courts The retraction and apology were forthcoming within the time limit*

I forward these examples of injustice not as a plea for help from the powers that be or should be, for non panel men have learnt to be self reliant, but simply as a further example of the curious fact that in borrowing this national insurance scheme from its makers the Government have gone the whole hog in the assimilation of German methods of ruthlessness mixed with bluff It has never been easy to tell what the General Medical Council might or might not hold to be infamous conduct Had they so considered the tearing up of the pledge and undertaking they might have saved the profession much loss of dignity and the general public much monetary loss and suffering, but they *apparently had no foreknowledge* of the importance since attributed to "scraps of paper" Such is the part played by time and chance in the *affairs* of men

Of the unpopularity of the National Insurance Act there are many signs, not the least significant being the spectacle of the Minister on whose shoulders *the mantle of* Elijah has been unloaded wandering in search of a safe seat

I am, Sir, yours faithfully,
FRANCIS HEATHERLEY,
Honorary Secretary Liverpool Non panel Union
Rock Ferry Jan 18th 1915

THE DIAGNOSIS OF PANCREATITIS

To the Editor of THE LANCET

SIR,—One heading only is absent from Sir Frederic Eve's Bradshaw lecture published in THE LANCET of Jan 2nd—not *that there* is either gap in *its* exhaustive treatment of the subject or thought of under rating the importance of diagnosis the omission is plainly descriptive of the present status of that rather essential chapter The ground is partly covered by the lecturer's remarks, an important fraction of it too by his suggestive diagram to guide the *operator* I need not trespass at much length upon your space, as there is little I can add to previous statements to which the references are subjoined[1] The diagram

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND

THE subscriptions to the Fund during the week ending Jan 19th have been good They include, it will be seen, a cheque received through Mr A A Tindall for £137 10s, being money mainly collected by Dr H Macnaughton Jones, and acknowledged in the *Medical Press and Circular* Dr Macnaughton Jones's endeavours on behalf of the Fund have been strenuous throughout, while he was one of the first supporters of the movement

The support of the Liverpool Medical Institution, which was promised from the beginning, has been substantial The subscriptions already received amount to £300, and it is hoped that, in reply to the appeal of the institution, a sum of money may be raised "worthy of the history and position of Liverpool as a great medical centre" Subscriptions should be sent at an early date to Dr T R Bradshaw honorary treasurer, at the Liverpool Medical Institution Professor Jacobs has accepted an invitation from the council of the institution to address the members of the medical profession on the circumstances and needs of his Belgian *confrères* at the Medical Institution on Thursday next, Jan 28th at 8 45 P M Cards of invitation to medical practitioners who are not members of the body will be supplied on application

The local committee in Birmingham has already made a handsome collection, £148 having been sent this week to Dr Des Vœux

International interest in the Fund has been stirred up and will not be lessened by the following episode The Belgian Society of Medicine in London at a meeting held on Monday last passed a vote of sympathy with the Italian sufferers in the recent terrible earthquake and requested that the money so far collected in Italy for the needs of Belgian doctors and pharmacists should be employed in alleviating the distress among the Italians

The appeal by Professor Jacobs on behalf of the medical profession in Belgium is sympathetically discussed in *Ugeskrift for Laeger* for December 17th This Journal is the official organ of the Danish Medical Association and it announces that the secretary of the association will receive contributions and forward them to the committee in England

The subscriptions to the British Fund which have been received up to Tuesday evening last by Dr Des Vœux in addition to £3120 already acknowledged are as follows —

comparability of the data involved is an indispensable condition, but in the present instance this precaution appears to have been neglected It is familiar knowledge that the army consists exclusively of picked men, chosen from their fellows after strict medical examination, the health and physique of the troops after enlistment having been raised as far as practicable by careful training as well as by suitable feeding and exercise and by hygienic environment We cannot compare the vitality of such troops with that of the general community, which includes large proportions of paupers, criminals, and other undesirable units, as well as of invalids and lunatics whose vitality and power of resistance to disease are manifestly inferior The common impression, which attributes exceptional loss of life to the forces engaged in modern warfare, is the right impression. "A. M D" concludes by offering helpful counsel to the host of probable sufferers from the present war in the event of its long continuance He emphasises the duty incumbent on every man, whether civilian or combatant, to make provision for his family against the possibility of his premature demise In a campaign of the present dimensions serious casualties are inevitable, but of the privation and distress thereby caused neither the incidence nor the intensity can possibly be foreseen The desirability of securing the needful protection by means of life assurance is one of the significant lessons of the existing European conflict

I am, Sir, yours faithfully,

Jan 18th 1915 MEDICAL STATISTICIAN

Obituary.

JOHN ROBINSON, L R C.P EDIN, L F P & S GLASG

THE recent death of Mr John Robinson, of Runcorn, removes a distinct personality He was greatly beloved and respected by those among whom he worked, and was typical of a class which would be styled old fashioned and out of date by the present generation Transfer Ian Maclaren's Dr Maclure from the Highlands to Runcorn, and substitute the bargees of Mr Jacobs for crofters, and the characters are identical His manner of dress would have been eccentric if worn by another, winter and summer a short, thick, double-breasted pilot cloth coat, buttoned up to the chin, afforded no opportunity for the display of linen, for which John Robinson had no use He wore no heels on his boots His head was covered with a shaggy thick crop of iron grey hair, and he was quite unconscious that his appearance differed from the man in the street

Having served an apprenticeship before commencing his scientific studies, he believed that the practical experience and knowledge of human nature acquired during this period was of infinitely more value than the preliminary scientific studies of the medical student to day His day's work, year in and year out, was not interrupted by week ends and holidays, for which he felt no need Busy morning and evening with surgery work and plenty of it, with long rounds in the afternoons Sundays and Bank Holidays not excepted, he was ready at any moment to tackle a case of difficult labour, to fight a pneumonia or perform an operation for strangulated hernia, for his clients could not afford the luxury of a specialist and his work had to be done with the assistance of a brother practitioner and the district nurse Instead of the appointments of an up to date surgical theatre, his operation room was often the bedroom in a cottage

A correspondent writes "He once showed me a knife carried among other miscellanies in his pocket with which he had done 20 hernias I asked him how many of the patients had died, he retorted not more than the average of a city hospital" His recreation was gardening and he regularly read his Greek Testament. Thus his life work was done day in and day out, assisting arrivals and easing departures, practising his profession as a vocation, not as a means of gaining wealth He used his power to help and his skill to advise those among whom his life work lay John Robinson would be more than content with the respect and affectionate memories of his friends, workers in humble spheres, rather than that of the so called upper classes

HUGH WARNOCK, M.R C P IREL, J.P

Mr Hugh Warnock, who died recently at his residence, Clogher, co Tyrone, as the result of an attack of cerebral hæmorrhage, was a native of the Dromore district of co Tyrone For the past 38 years he practised in Clogher, where he was dispensary medical officer and medical officer of health He was also medical attendant at the workhouse hospital for the past 13 years, and a magistrate for co Tyrone A skilful practitioner of medicine, a thorough man of business, and generally popular, Mr Warnock will be very much missed

ETHEL FRANCES LAMPORT, M.D BRUX, L S.A

WE regret to learn that Dr Ethel Frances Lamport died very suddenly on Dec 27th, 1914, whilst driving to church Miss Lamport entered the London Hospital as a probationer in 1884, and after completing her training was made sister of one of Sir Frederick Treves's wards, a post which she held for several years After leaving the London Hospital Miss Lamport took the diploma of sanitary inspector and then decided to study medicine, entering the London (Royal Free Hospital) School of Medicine for Women in 1891 On qualifying Dr Lamport at once returned to the East end of London and began to practise in Bow, where she worked unremittingly for over 11 years for the improvement of the physical and social conditions of the women and children who came under her care She also held the post of public vaccinator in Millwall (Isle of Dogs) for 10 years When failing health made it impossible for Dr Lamport to continue her arduous life of work amongst the sick poor, she retired to Well Manor, near Long Sutton, Hampshire, where she quickly endeared herself to her neighbours by her genial manner and the kindly interest she took in them Dr Lamport will long be remembered in Bow and Poplar for her unselfish devotion to the sick poor in those districts

ROYAL COLLEGE OF SURGEONS OF ENGLAND — At a meeting of the Council of the College held on Jan 14th the diploma of M R C S was conferred upon Mr Stephen Abraham Liebson of Guy's Hospital and licences to practise dental surgery were granted to Mr Percy Gordon Burlo-Griffin, of Liverpool University and Mr Harry At[illegible] Hutson of Middlesex and National Dental Hospitals all of whom have complied with the regulations

spent in providing compact storage space for breakable glass apparatus and delicate instruments without risk of damage from jolts and bumps when the car is on rough roads. The investigator indeed has everything he is likely to want for ordinary purposes almost immediately under his hands. Three previous laboratory cars which have been equipped by Messrs. [illegible] and Taylor for the War Office during the progress of the war are already in use with the Expeditionary Force and various improvements in design [illegible] which provides a mobile means of fetching pathological fluids and specimens from points nearer the firing line than the car itself would ordinarily reach. Captain A. C. H. Gray, assistant professor of pathology at the Royal Army Medical College, is in charge of the laboratory, which has already left for an oversea base. On Monday last Captain Gray was received by Princess Christian at Schomberg House and the laboratory car was inspected by Princess Victoria of Schleswig-Holstein. Our illustrations give an outside view of the laboratory car and side-car, and an interior view of the laboratory taken from the door at the back of the car.

Medical men and pharmacists and other kind supporters of the Fund in the Liverpool area should send their subscriptions to Dr T R Bradshaw, at the Liverpool Medical Institute

THE APPEAL FOR SURGICAL INSTRUMENTS

The Master of the Society of Apothecaries acknowledges with thanks the receipt of surgical instruments kindly contributed by the following gentlemen since the publication of the last list —

Dr F R B Atkinson, Warwick street London S W Mr John W Orviss, Jersey, Dr Blair, Jedburgh, Dr Selwyn Edwards, West Bromwich, Dr Basil Hounsman, Tardebigge, near Bromsgrove, Dr R Anderson, Erdington Birmingham, Dr S Bodger, Studley, Warwickshire, Dr E Cautley Park street, Park lane London, W, Dr W H Lewis Llansantffraid, Mon

Subscriptions to the Fund should be made payable to the Belgian Doctors' and Pharmacists Relief Fund, crossed Lloyds Bank, Limited, and sent to Dr H A Des Vœux, 14, Buckingham gate, London, S W

The War.

THE PRINCESS CHRISTIAN MOTOR LABORATORY

THROUGH the generosity of an anonymous donor a fully equipped motor bacteriological laboratory has been placed this week at the disposal of the War Office for service at the front The car, which will be known as the "Princess Christian Motor Laboratory," consists of a large van shaped body divided into two compartments, with driver's seat in front, on a 20–30 h p Clement Talbot chassis The outside body work of the coach was built by Messrs Peters and Son, of Acton, and the internal construction, fittings, and scientific equipment have been devised and carried out by Messrs Baird and Tatlock, Limited, under the supervision of Mr Douglas Baird

The main laboratory—6 ft 6 in long by 6 ft wide—is entered through a door at the back, and is fully equipped with glass covered bench top, sink, centrifuge, balances, microscope, bookshelf, water cistern, and so on, with shelves, drawers racks, and cupboards containing reagents, microscopical stains, and all the necessary apparatus for bacteriological and cytological work. The smaller compartment—2 ft 10 in in depth by 6 ft wide—is separated from the laboratory by sliding doors, and contains two incubators, hot air and steam sterilisers, still and condenser, autoclave and water bath, together with a fume cupboard with electric fan beneath to drive out impure air and gases The necessary heat for these appliances is provided by Primus burners and intensive oil lamps, while a petrol incandescent lamp supplies enough heat to warm the laboratory in winter Electric current for general and microscopical illumination is obtained by a dynamo belt driven from the engine The height of the laboratory at the centre is 6 ft 6 in, and there is enough floor space in the middle of it to give impromptu sleeping accommodation for the bacteriologist if need arises The driver's platform can be closed in by screens, and a trap lets down above the seat, thus furnishing two bunks one above the other in which the driver and laboratory assistant can sleep The total weight of the car with driver, is 3 tons 8 cwt, and the cost has been upwards of £2000

The manner in which this travelling clinical laboratory has been designed and fitted up, so as to give the fullest working outfit in the smallest space consistent with freedom of movement, is deserving of high praise Much ingenuity has been desirous of enlisting as soon as their teeth are in order The Soldiers Dental Aid Fund, with offices at 36, Liecester-square, London, W C, has been established for a similar purpose and has the support of the Presidents of the Royal Dental and National Dental Hospitals

4TH LONDON (CITY OF LONDON) GENERAL HOSPITAL.—This Territorial General Hospital unlike its fellows in the London District, occupies buildings expressly designed and constructed for use as a hospital The original plan before war broke out, was that the site of the hospital on mobilisation should be at St Paul s School, but this idea was abandoned early in August in favour of transforming the greater part of the new King s College Hospital at Denmark Hill into a military hospital The whole institution in its double capacity as a military and civil hospital has now been in full working order since within a week of the order for mobilisation, the military side of it being under the able direction of Lieutenant-Colonel Nestor Tirard, the Commandant Although the entire hospital building, as designed, has not yet been completed the hospital authorities have been able to place at the disposal of the War Office sufficient accommodation to provide a fully equipped military hospital of 520 beds, and to these have been added 114 additional beds as the need for expansion arose A very large number of military patients are also received under the administrative control of the 4th London General Hospital authorities in five other London hospitals in the east the north and the west At King s College Hospital the casualty block and six wards on the first floor remain for civilian use and for the medical school The rest of the buildings are military, and the full use of the whole equipment of the hospital is at the disposal of the military medical authorities the War Office paying for the upkeep of those portions of the hospital which have been handed over to them The staff of the 4th London General Hospital is drawn from the medical and surgical staffs of King s College Hospital, St George s Hospital, Charing Cross Hospital and Westminster Hospital Colonel Tirard is assisted in his administrative duties by Major G N Biggs and the Quartermaster Captain J Boxall Of the a la suite staff of medical officers available for service on mobilisation the following have already been called up for duty Lieutenant Colonels Norman Dalton and Stanley Boyd, Majors A. H Tubby F W Mott W G Spencer A Carless W Aldren Turner and J Galloway, Captains A M Gossage, H F Waterhouse, Cyril Ogle Arthur Latham, William Turner, William Hunter, W C Bosanquet A H Evans J S Collier, H S Pendlebury J Purves Stewart E R Carling T Crisp English, R O Sibley W D Este Emery and R Knox The principal wards of King s College Hospital, which are built on the pavilion system are admirably suited for the use of military patients and the modern construction and equipment of the new hospital are of the greatest possible advantage to all concerned

BRIGHTON MILITARY HOSPITALS A TRANSPORT

evacuated of their usual inmates on Jan. 16th, when the keys were handed over to the Government representatives, and active preparations are being made for the reception of wounded Indian soldiers, elaborate alterations being necessary in both the sanitary and cooking arrangements The institution is now officially known as Kitchener's Hospital, and on Jan 12th there arrived from Bombay the personnel of five field hospitals and two hospital ships, comprising 25 English officers, 26 Indian officers, 41 warrant officers (Indians) and 544 men (Indian soldiers), the latter including attendants, cooks, &c, for both Mohammedan and Hindu The occupation of this hospital by wounded Indians is not expected for some time"

BRITISH HOSPITALS FOR THE BALKANS —The British Red Cross is sending out two hospital units one to Serbia and one to Montenegro The unit for Montenegro consists of Dr F G Clemow C M G, in charge, with Dr Virtue Tebbs and Dr Burnham as surgeons, two trained nurses two Voluntary Aid Detachment ladies, and four male orderlies The unit will proceed first to Malta, whence it will make every endeavour to reach Montenegro A large quantity of medical stores is being taken, and, owing to the conditions prevailing in Montenegro, the unit is compelled to carry with it food, &c, for six months, so as to be independent of local supplies A hospital unit for Serbia is also leaving London under the superintendence of Mr James Berry, senior surgeon to the Royal Free Hospital The unit has the direct authority of the Serbian Government, and the British Admiralty has consented to transport it free of cost A full medical and surgical outfit will be carried, while clothing and other comforts for the people of Serbia will also be taken, so far as funds permit The medical staff consists of Mr James Berry, senior surgeon and medical superintendent, Mr Laurence E Panting, surgeon, Mrs F May Dickinson Berry, physician and anæsthetist, Dr Ernest V Williams, radiographer, Dr Dorothy Chick, house surgeon, and Miss K M Parkinson, dresser, together with 8 nurses under Miss Irvine Robertson, 5 lady orderlies, 4 orderlies, and a cook

THE FRENCH AUTOMOBILE AMBULANCE NO 1 —Our Paris Correspondent writes that on Jan 13th Dr Hallopeau laid before the Société de Chirurgie statistics of the results obtained with automobile ambulance No 1, which was supervised by himself in conjunction with a surgical colleague of the Paris hospitals whose idea it was, and who acted as médecin chef of this new sanitary formation The object was to provide a surgical establishment in which operations could be done with as much certainty of surgical technique as in the most modern hospitals, and as near the firing line as possible This was accomplished in the most scientific yet simple manner imaginable The entire formation consists of three light wagons and an engine This last contains the most important part of the ambulance the steam generator, which assures at any hour of the day or night an adequate supply of perfectly sterilised

GERMANY AND AUSTRIA IN WAR TIME

A medical correspondent, writing from Switzerland on Jan 15th, sends us the following notes of scientific and professional affairs in Germany and Austria, gleaned from the medical press of those countries since the New Year

It might be of interest to try to form some idea of the way in which five months of war have affected the German medical world The medical papers all appear regularly and have their usual external appearance, although slightly decreased in size, especially in the advertisement columns Most have special military supplements, but the text of the journals is by no means exclusively military, and turning to the pages of the Munich journal one reads of complement reactions and of tuberculin, followed by a case of suture of the right ventricle from a sabre cut during a quarrel, an illustration of the seamy side of militarism The British journals naturally figure no longer in the summaries of current literature, although a Vienna paper continues to use American sources freely as well as the journal of the Royal Army Medical Corps It is unfortunate that, although prominence was given to the complaint of the Hamburg doctors against the conditions supposed to prevail among the interned Germans in England, no notice has been taken of the effective replies to this published in THE LANCET and *British Medical Journal* The medical societies continue to meet at the principal university centres, while the character of the communications is largely dependent on proximity to the fighting line A reunion at Lille (which is explained by the papers to be in France !) naturally discusses bullet and other wounds Explosive bullets still figure *ad nauseam* and it is refreshing to meet the following paragraph "The doctor can often help to set the soldier's mind at rest by correcting his frequently erroneous opinion that he has been wounded by an explosive bullet. To be wounded is hard enough, but the feeling of being the victim of the enemy's baseness is harder still, and when not justified by facts should be removed, if possible, in the interest of the wounded man himself" At the universities nearly the usual number of students have been enrolled, but a large proportion of these are away on war leave Here, again, the towns nearest the front are most depleted. At Strasburg, for instance, 535 out of 1155 students are at the front, at Bonn 1117 out of 4518 The new university of Frankfurt on Main, which was inaugurated by an Order in Council signed by the Kaiser on June 10th, 1914, was opened without ceremony in October, and although ten of the new professors were at once called to the front, the well known names of Quincke and v Noorden appear as professors and 80 medical students were enrolled Amid the shout of arms time has been found to celebrate the 400th birthday of Vesalius, the founder of anatomy, with an exhibition at Berlin, which might indeed now have been conducted at his birthplace, Brussels

The health of the German army continues to be reported as excellent, but certain grave risks are not far distant Typhus has broken out among the Russian prisoners at the camp at Cottbus with several hundred cases, prevented so far by rigid isolation from spreading outside the camp, but Professor Jochmann, of Berlin, fell a victim to the disease whilst conducting a Government inspection On the Eastern frontier the soldiers are recommended to carry 30 to 50 grammes of naphthalin to keep off body parasites in order to avoid possible infection, but it is doubtful whether the supply of this drug is sufficient to make the suggestion practicable In the last report there were 166 cases of cholera among the Russian prisoners in Germany, but only 1 Englishman, 10 German soldiers, and 2 German civilians have been infected. In Austria the disease appears to be less prevalent although during three months in a single Vienna hospital 2800 stool examinations were made, and vibrios were found in 250 persons Attention is called to the great danger of cholera carriers—i e, cases coming from infected areas with only slight symptoms In general the health of the prisoners is also reported to be good, but bitter complaint is made of the difficulty of sparing food for the number of these which is stated to be 600,000, and attention is called to the urgent need of sending the unfit ones home The food supply in general continues to give rise to anxious thought A medical writer discusses at length the practical aspects of the question remarking what a large part the food supply plays in the effectiveness of the army, regretting that the potato harvest was not so good as was expected, and emphasising the great advantage that the army is on enemy's soil whilst the family at home eats proportionally less He advocates the working out of the experience of both the productive and hygienic side of the nation's supply and the enforcing its observance by law In Berlin it has so far been impossible to persuade either the bakers to bake or the population to eat, the prescribed bread containing 10 per cent of rye flour, and the prospect of a shortage in wheat-supply is increasingly imminent. The lack of drugs in Germany has apparently not been severely felt so far, although morphia and other opium alkaloids have doubtless been replaced where possible by synthetic remedies in ordinary practice, morphia itself being left largely for the relief of the wounded Stress is laid on lack of drugs in Russia, where there is said to be no manufacture of pure chloroform for anæsthetic purposes nor of iodine and its derivatives, but an expedition is stated to have been sent to the White Sea to procure a stock of iodine from the seaweed there Another medical writer states with apparent seriousness "We must free ourselves from our exaggerated German reserve, solicitude and conscientiousness even bordering on pedantry" in order to ensure rightful demands The intellectual ability of the German doctor is further illustrated by a serious discussion of high medico-legal authorities as to the ownership of bullets extracted by operation from wounded men On the one side it is argued that after shooting a bullet the enemy surrenders his property in it without conferring it upon his opponent, in whose body it therefore remains as only lost, as it is not an integral part of his tissue But in no case can the doctor take possession of it without permission Another grave authority considers that the bullet still remains the property of the hostile side

---

THE BRITISH RED CROSS SOCIETY —In its summary of work for the week ending Jan. 16th the British Red Cross Society states that during the past week there have been despatched to Boulogne 6 ambulances, 1 motor cyclist, and 1 lorry, to Dunkirk 4 ambulances and 2 touring cars, to Calais 1 lorry, and to various places in England 12 ambulances The number of auxiliary home hospitals accepted by the War Office up to Jan. 16th is 686 containing beds for 19,159, including 377 beds accepted during the past week. At present at Netley Hospital there are 145 British, 8 foreign invalids, 6 Belgians, and 240 Indians in hospital. One death has occurred among the Indians from pneumonia. The new hospital for nurses is being erected and the buildings of the Irish Hospital are progressing and will be brought into use at the end of the month. 1490 cases of stores were sent abroad during the week, of which 1259 were despatched to Serbia and Montenegro Fifty hospitals in this country were supplied with 252 cases of stores and garments The number of patients who have been treated in the British Hospital during the eight weeks it has been opened now total 873—namely, British, 50 officers and 816 of other ranks, and seven German prisoners. Two orderlies left for Serbia on the 16th, and one clerk for Boulogne, also three cooks for Boulogne. During the week 24 nurses were posted for home service and one despatched for foreign service

VACANCIES FOR MEDICAL OFFICERS —Major C M Fegen, R A.M C (T F), divisional sanitary officer of Reigate, asks us to state that medical officers are needed in his command both for field ambulances and for regimental work Applications for commissions should be made to Captain Cave, Officer Commanding Depôt (Medical Units), Duke of York's Headquarters, Chelsea London S W —In our Service column this week an announcement is made that the War Office has several vacancies for temporary lieutenants in the Royal Army Medical Corps

SIR WILLIAM OSLER, according to a telegram from Montreal, has offered his services to the McGill University base hospital which is now being organised for duty at the front.

DENTAL AID FOR SOLDIERS —The trustees of the late Sir William Dunn have made a grant of £1000 to Guy's Hospital to be applied for the treatment of the teeth of soldiers now serving with the British forces and of men

The resolution also provided for the sending of a circular to practitioners explaining and deprecating the delay thus arising in remitting payments and urging that an intimation of the regret of the Committee at their inability to make prompt payment should be conveyed to the Commissioners. The delay was denounced in strong terms in the course of the discussion and in connexion with the adoption of the minutes and reference was also made to another matter in which the medical profession was hardly treated. This arose out of a letter from the Commissioners stating that the concessions made to druggists with regard to the increased cost of drugs through the war were not applicable to practitioners on the panel who had arranged to dispense medicines to their insured patients on a capitation basis.

Medical Magistrate.—Dr. Frederick Wolverson has been appointed a justice of the peace for the county of Stafford.

Anthrax in Aberdeen.—A case of anthrax has occurred in Aberdeen, the victim being a woman who was engaged in mending bone meal bags. She returned from her work an hour earlier than usual on Dec. 3rd last complaining of feeling unwell. The glands of her neck were very much swollen. On the next day she went to her work but returned much worse. A medical man was sent for and her condition gradually became worse, death supervening on Dec. 8th. During the inquiry under the Fatal Accidents Inquiry Act the medical practitioner who attended her said that her mouth was in a septic condition and it was possible the germs might have found entrance by the septic gums or the disease might have been contracted through rubbing the bone dust into a scratch or broken pimple. The jury found that the woman had died from anthrax contracted accidentally.

Donations and Bequests.—Subject to the life interest of his wife the late Mr. Thomas S. D. Wallace of Brighton left by will £1000 each to the London Hospital, Guy's Hospital, the Homœopathic Hospital, the British Home for Incurables at Streatham, and the Cancer Hospital at Fulham.—The Royal Dental Hospital, Leicester-square, has received a donation of £100 from the Worshipful Company of Goldsmiths.—By the will of the late Mr. H. Mitchell of Birmingham the testator left £6700 upon trust to apply the income for the benefit of the Birmingham Athletic Club for the provision of annual lectures on health and hygiene during the 21 years following his decease and subject thereto this sum is to be divided as to one-third to the Queen's Hospital, Birmingham, one-fourth to the Birmingham and Midland Eye Hospital, one-fourth to the Birmingham and Midland Skin and Urinary Hospital, and one-sixth to the Birmingham Athletic Institution.—Among recent donations to the fund for the extension of the London (Royal Free Hospital) School of Medicine for Women are £262 10s. from the Mercers' Company and £50 from the Goldsmiths' Company.

Infectious Disease in Belfast.—At the January monthly meeting of the corporation of Belfast officer of health did not get a free hand or insist on his advice being acted upon. The necessity of weekly cleansing of every national school in the city was considered. A medical councillor having pointed out that there was a diminution in the number of scarlet fever cases even before the closing of the schools added that it would be interesting to find how far closing of the schools contributed to the diminution of the scarlet fever epidemic. It is a healthy fact to find the public health of Belfast being discussed by its civic fathers; it means that the public of Belfast are showing clearly that they are far from being satisfied with the present condition of the health of the city.

Medical Barrister.—Dr. W. E. St. Lawrence Finny, J.P., who is a member of the Inner Temple, has passed the Bar Final Examination, qualifying for admission as a barrister-at-law.

Leicester Royal Infirmary.—At a quarterly meeting of the governors and subscribers held on Wednesday last it was decided to build and equip a new and complete pathological and clinical laboratory and post-mortem department at an approximate cost of £3500.

Royal Meteorological Society.—The annual general meeting of this society was held on Wednesday evening last at the Surveyors' Institution, Great George-street, Westminster, when Captain H. G. Lyons, F.R.S., was elected president, and Mr. F. Campbell Bayard and Commander W. F. Caborne, C.B., secretaries for the ensuing year. The new members of council are Mr. J. S. Dines, Mr. A. P. Jenkin, and Sir J. W. Moore, M.D.

Hunterian Society.—On Wednesday, Jan. 27th, a visit will be made by the members to the Pathological Department of St. Bartholomew's Hospital, where tea will be served at 4 P.M. in the Kan back Library. The following demonstrations will be given: Dr. Mervyn H. Gordon, The Technique of Wassermann's Reaction; Dr. Mackenzie Wallace, (1) The Estimation of Blood Sugar in Diabetes, and (2) Abderhalden's Serum Diagnosis of Pregnancy; Dr. A. E. Stansfeld, The Projectoscope as a Method of Showing Pathological Specimens; Dr. J. W. Trevan, Recent Additions to the Hospital Museum; Dr. G. Graham, The Estimation of the Alveolar CO; Dr. Langdon Brown and Dr. A. Feiling, A Tumour of the Mid-brain.

Mr. William Hichens died at his residence in Redruth, Cornwall, on Jan. 15th, in his fifty-first year. He was a son of the late Dr. J. Harvey Hichens, and was educated at Epsom College and the London Hospital Medical School. He held several appointments at Redruth, being surgeon to the West Cornwall Miners' Hospital and Hospital for Women, and was also medical officer for the workhouse infirmary and public vaccinator. He was greatly interested in football and was for 15 years president of the Cornwall Rugby Union. When at the London Hospital he was captain of the cricket and football teams. He was extremely popular in Redruth and the district and much sympathy is felt there for his widow and the abdomen have been operated upon, of which three were cured The surgeons have operated in it for ten hours in succession

SOLDIERS' DREAMS —A correspondent in charge of an ambulance on the Continent, when his time was not fully occupied by surgical emergencies, has had the curiosity to inquire into the psychical consequences of the emotions inseparable from active fighting as shown in dreams and other subconscious manifestations Neurotic subjects, as one would expect, he says, react in a most striking fashion to the shock of explosions in their immediate vicinity Some develop a tendency to somnambulism and are met wandering about the premises with terror and anxiety depicted on their faces in anxious search of their regiments Short of somnambulism the dread of losing contact with their fellows seems to be felt with extreme frequency, and horror of isolation constitutes the commonest nightmare of men in the first fighting line They dream that they are wandering through endless trenches as complicated as an artificial maze, or are picking their way through lonesome forests whence all but they have fled The slightest noise during sleep calls up visions of exploding shells or the tramp of armed men, throwing them into a frenzy of shouting terror, to the indignation of their resting fellows Oddly enough, these men are as brave as the rest in face of real danger Another common night terror is the dream of a sudden call to arms and the inability to find some indispensable article of attire or combat, a conception productive of intense mental agony Live shells naturally occupy a large share of subconscious attention, and an exasperating nightmare is the discovery in one's bed of a shell ready and willing to burst, associated with the usual nightmare incapacity to execute the necessary movements to get rid of it Several men have had dreams centring round the inability to withdraw the bayonet from the enemy's body when urgently required for self defence Numerous instances of "traumatic hysteria" are met with in which men, suddenly roused from deep sleep by explosions, develop the characteristic paralyses and disturbances of sensation In one case there was marked limitation of the field of vision and inability to connect letters into words, the man could read the letters, but could not pronounce the word when spelled nor write the word when pronounced Insomnia and more or less troublesome restlessness are also common consequences of the strain on the nervous system of actual warfare

ROYAL COLLEGE OF SURGEONS IN IRELAND AND THE WAR.—The President, Vice President, and Council of the Royal College of Surgeons in Ireland have decided to place in the College a permanent record of the names of all the students, Licentiates, and Fellows of the College who are at present serving with His Majesty's Navy and Expeditionary Forces and further to erect a suitable memorial to all such as fall in the war Relatives and friends are invited to communicate the names of such students, Licentiates, and Fellows to the Registrar of the College, Dublin

IRISH MEDICAL MEN AND THE TERRITORIAL FORCES —Dr J C McWalter, governor of the Apothecaries' Hall of Ireland, writes 'May I appeal through your pages to the army authorities to give Irish doctors the same facilities for serving their country as are enjoyed by our British brethren? In Great Britain a very large proportion of practitioners belong to the Territorial Forces It may not be possible for them to go to the front but they are doing active service and if an emergency occurred would doubtless be ready to go where wanted In Ireland we have no Territorial Forces and though a very large number of our younger men have volunteered and a great many are in the Officers Training Corps there appears to be no opportunity for medical men above the age of 45 of joining any branch of the Army Medical Service except in a few isolated instances

BRITISH PRISONERS IN GERMANY —A correspondent in Switzerland writes — 'An interesting report on the condition of the French and British prisoners in the concentration camps of Germany has just been presented to the International Committee of the Red Cross Society at Geneva by Dr Ferriere and M Gustave Ador The two Swiss delegates spent a considerable time in Germany where the authorities apparently did their best to make their task of investigation both pleasant and easy The report lays emphasis on the fact that the enforced confinement does not seem to be having any ill effects upon the health of the prisoners The moral sufferings which the régime of complete isolation occasions the officers are it is pointed out, considerable The inaction which now characterises their lives—as contrasted with the strenuous vivid life on the fields of battle—also weighs heavily upon them They are allowed no newspapers, very few books, limited and very colourless correspondence. From the point of view of sanitation and organisation it is stated the great concentration camps in the neighbourhood of Berlin are entirely admirable The wooden dwelling houses are well built, are provided with double walls, and are comfortably heated Long corridors suitable for exercise divide the rows of dwellings, and in the centre of the camps a canteen, where cigars, warm clothing and food and delicacies were sold, was generally found The delegates regret that unfounded reports, based probably upon individual cases which had no general significance in regard to the concentration camps in Germany have been given publicity The material conditions of captivity, their experience indicated, are satisfactory The ordinary diet of the prisoners is that of the German soldiers "

Count Lalaing, the Belgian Minister in London, has sent a letter to the Vice Chancellor of the University of Cambridge expressing grateful appreciation to the Senate of the University for their generous hospitality to professors from the Universities of Louvain, Liége, and Ghent, and to a number of students unfitted for military service with the Belgian army

EAST SUSSEX INSURANCE COMMITTEE —At a meeting of the East Sussex Insurance Committee protest was raised by medical men present at the delay taking place in the making of payments to practitioners on the panel final credits for 1913 as well as provisional credits for 1914 being still unsettled The Commissioners had issued a circular to medical men intimating that the Insurance Committee would make no further advance until the practitioner in question had furnished the required records and the making of proper returns had been recently rendered in many cases impossible owing to the war and the loss of cards in transmission A resolution passed by the Medical Benefit Subcommittee provided for the drawing and signing of cheques by the Committee after examination and approval of the amounts payable but recognised the intervention of the Commissioners by providing that his cheque should not be sent to a practitioner until the Commissioners notified the Committee that they had received the lower halves of his record cards from him

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.—Temporary Junior House Physician. Salary £100 per annum, with board and residence.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—House Surgeon. Salary £150 per annum, with board, residence, and laundry.

HALIFAX ROYAL INFIRMARY.—Second and Third House Surgeons, unmarried. Salary £120 and £100 per annum respectively, with residence, board, and washing.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.—Anæsthetist. Salary 50 guineas per annum. Also Assistant Resident Medical Officer. Salary £100 per annum, with board and residence.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Two House Surgeons, unmarried, for six months. Salary £30, with board, residence, &c.

HULL, VICTORIA CHILDREN'S HOSPITAL, Park-street.—Female House Surgeon and Female Assistant House Surgeon. Salary £60 and £50 per annum respectively, with board and laundry.

LEEDS PUBLIC DISPENSARY.—Female Resident Medical Officer. Salary £130 per annum, with board, residence, and laundry.

LEICESTER BOROUGH SANATORIUM AND TUBERCULOSIS DISPENSARY.—Assistant Medical Officer. Salary £300 per annum.

LEICESTERSHIRE EDUCATION COMMITTEE.—Temporary Assistant School Medical Officer. Salary at rate of £300 per annum.

LEWES, EAST SUSSEX COUNTY COUNCIL EDUCATION COMMITTEE.—Assistant School Medical Officer. Salary £320 per annum.

LIVERPOOL, CITY OF.—Female Assistant Medical Officer. Salary £350 per annum.

LIVERPOOL STANLEY HOSPITAL.—House Surgeons and Physicians.

LLANELLY BOROUGH EDUCATION COMMITTEE.—Ophthalmic Surgeon. Salary £50 per annum.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W.—Assistant House Surgeon for six months. Salary at rate of 100 guineas per annum.

MANCHESTER CHILDREN'S HOSPITAL, Pendlebury.—Visiting Surgeon. Salary £100 per annum.

MANCHESTER, COUNTY ASYLUM, Prestwich.—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, apartments, attendance, and washing.

MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT AND CHEST.—Assistant Medical Officer for the Crossley Sanatorium, Delamere Forest, Cheshire. Salary £100 per annum, with board, apartments, and laundry.

MANCHESTER HULME DISPENSARY, Dale-street, Stretford-road.—House Surgeon. Salary £120 per annum, with apartments, attendance, coal, and gas.

MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park place, Cheetham Hill-road.—House Surgeon. Salary £120 per annum, with apartments and board.

MANCHESTER ROYAL EYE HOSPITAL.—Junior House Surgeon. Salary £80 per annum, with residence, board, and washing.

MANCHESTER ROYAL INFIRMARY.—Five Junior House Surgeons for three months. Board, residence, and laundry provided. Two Senior House Surgeons for six months. Five House Physicians for three or six months, and One House Surgeon to Ear, Eye, and Gynæcological Departments for six months. Salary at rate of £[illegible] per annum, with board, residence, and laundry. All to be unmarried. Also Two Medical Officers for Out-patients and Accidents for six months. Salary at rate of £100 per annum, with board and residence. Also Accident Room House Surgeon for six months. Salary £100 per annum, with board and residence.

MANCHESTER, ST. MARY'S HOSPITALS FOR WOMEN AND CHILDREN.—Resident Surgical Officer at High-street Hospital. Salary £[illegible] per annum, with board and residence. Also House Surgeon for three or six months. Salary at rate of £70 per annum, with board and residence. Also House Surgeon at Whitworth-street West Hospital for three or six months. Salary at rate of £70 per annum, with board and residence.

MANCHESTER, VICTORIA MEMORIAL JEWISH HOSPITAL, Cheetham.—Female Resident Medical Officer for six months. Salary at rate of £100 per annum, with rooms, board, and laundry.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—Two Assistant House Surgeons for six months. Salary at rate of £[illegible] per annum, with board and washing.

MIDDLESBROUGH COUNTY BOROUGH.—Temporary Chief Tuberculosis Officer.

MIDDLESBROUGH EDUCATION COMMITTEE.—Temporary Assistant School Medical Officer. Salary £300 per annum.

MILLER GENERAL HOSPITAL FOR SOUTH EAST LONDON, Greenwich-road, S.E.—Junior House Surgeon for six months. Salary £[illegible] per annum, with board, residence, and laundry.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index and Title page to Vol. II of 1914 were given in THE LANCET of Dec 26th, 1914

VOLUMES AND CASES

VOLUMES for the second half of the year 1914 are now ready Bound in cloth, gilt lettered, price 16s, carriage extra.

Cases for binding the half year's numbers are also ready Cloth gilt lettered price 2s, by post 2s. 3d

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows —

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs 50 per month.)

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

TO COLONIAL AND FOREIGN SUBSCRIBERS

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied

SOLE AGENTS FOR AMERICA—MESSRS WILLIAM WOOD AND CO, 51, Fifth Avenue, New York, U S A.

Notes, Short Comments, and Answers to Correspondents.

CAMPAIGN LITERATURE AGAINST VENEREAL DISEASE

SPEAKING before the Royal Commission on Venereal Diseases, Sir Thomas Barlow expressed his belief that the public mind was now in a state of most promising preparedness to receive admonition and to recognise the moral obligation of dealing with these subjects In 1913 a declaration of leading members of the medical profession in the daily press protested against the "conspiracy of silence" on the subject. Mr F W Giles, M B Durh, a member of the council of the White Cross League, has published through Messrs P S King and Son, price 6*d*, a little pamphlet on "The Campaign against Syphilis, which seems a suitable contribution to the task of public enlightenment It deals with the nature and effects of venereal disease and with the importance to the community of its treatment and prevention It is dedicated by permission to Sir Thomas Barlow

THE "PERMUTIT" SYSTEM OF WATER SOFTENING

AN interesting demonstration of improved methods of water softening was given at the offices of United Water Softeners, Limited Imperial House, Kingsway, London W C, on Jan 12th The "permutit" system may be described first, as its simplicity enables it to be applied locally for domestic purposes Permutit is substantially an artificial zeolite, a compound of silica, alumina, and soda Its essential property is that known as base exchange In contact with hard water, for example (the calcium and magnesium salts constituting the hardness), permutit effects an exchange It abstracts these salts in exchange for a soda complement, so that hard water passed through it becomes soft because the lime and magnesium salts are left behind and the corresponding sodium salts go forward. The action is perfectly automatic, and when the soda permutit is exhausted it may be regenerated by passing through the permutit column or cylinder some salt solution, when the calcium and magnesium are eliminated as chlorides in favour of the retention of soda permutit ready again for the treatment of further volumes of hard water This method is capable of reducing a water of a high degree of hardness to one showing no hardness at all, and which therefore instantly forms a lather with soap In some cases the permutit system is employed to finish the work of well known economical softening methods, as, for example, those depending upon the addition of lime or of black ash (crude carbonate of soda). The utmost efficiency of these chemical methods in removing lime and magnesium salts is, however, reached when the treated water still retains some 5 degrees of hardness The water so far softened is reduced to an imperceptible hardness when it is passed through the permutit column By a combination of these processes, the "Lassen Hjort" and the permutit, an economical and complete softening of the water is effected For domestic work all that is necessary is a permutit cylinder, and a very favourable impression of its efficiency has been made upon those occupying houses situated in hard water districts where it has been installed. When treated with manganese permutit takes iron completely out of water The advantages of a softened water supply need not be set out In our own columns we have often drawn attention to the hardships of a hard supply, but we think that the consumer should not be called upon to remedy the evil and that this is a duty which should fall upon the supply company So long however, as that is not the case, permutit will effect a revolution of the utmost value to the householder

PERSONAL MEDICINE CASE FOR USE ON ACTIVE SERVICE

SINCE the commencement of the war medical men have frequently been asked for advice upon the selection of medical equipments for personal use whilst on active service and in view of this Messrs Burroughs Wellcome and Co have introduced 'Tabloid" Brand Medicine Pocket case, No 109 which is specially adapted to meet the requirements of those serving with His Majesty's forces The contents of this case may be varied to order so that the medical man may prescribe the particular products which he considers best suited to the individual needs of his patient The case itself is of polished black japanned metal In design it is flat and similar in shape and size to a large pocket cigar-case Consequently it fits conveniently into the pocket of the service jacket, its rounded corners preventing any risk of tearing the material The tubes of 'Tabloid" and "Soloid" medicaments are securely held in position by an aluminium framework, divisions of which come between the phials thus obviating the use of loose packing In the case of liquids each glass container is enclosed in a metal case rendering it impossible for any of the contents to leak out and soil other products. Further particulars may be obtained from Messrs Burroughs Wellcome and Co on application, together with a list of standard contents, which include both medicinal and first aid requisites

HOW TO PRESERVE HEALTH IN WAR TIME

THE Women's Imperial Health Association of 7, Hanover square, W, have issued a word in season to the women of Great Britain in the shape of a four page leaflet entitled "Health in War Time" It consists of useful information under the following heads Keep the Homes Clean; Keep Ourselves Clean, Get to Love Fresh Air, Eat the Right Food, Drink the Right Drinks, Cultivate Regular Habits, Help to Prevent Epidemics, and Take Care of Our Convalescent Soldiers How we may all do these things and thus help the Empire is explained in the leaflet

COMMUNICATIONS not noticed in our present issue will receive attention in our next

Medical Diary for the ensuing Week.

An Address

ON

THE TELEPHONE ATTACHMENT IN SURGERY

Delivered before the Medical Society of London on Jan 25th, 1915

BY SIR JAMES MACKENZIE DAVIDSON,
M B, C M ABERD,

CONSULTING SURGEON TO THE ROENTGEN RAY DEPARTMENT
CHARING CROSS HOSPITAL

GENTLEMEN —My attention was first called to the possibility of using the telephone in surgery by a leading article in THE LANCET 32 years ago[1] The article was concerned mainly with the attempts which had been made to determine by electrical means the position of the bullet in the body of President Garfield during the two months which elapsed between the infliction of the wound and his death in the summer of 1881. These attempts were made with an induction balance, but Professor Graham Bell, speaking afterwards at a meeting of the American Association for the Advancement of Science, suggested, according to THE LANCET, that —

> Either for the detection of bullets or for the estimation of the depth of a ball already localised by the induction balance a simpler electrical contrivance may be employed It consists of a telephone, to one terminal of which a fine needle is fixed, and to the other a plate of metal of the same nature as the needle. The plate is placed on the limb to be examined and the needle is thrust in where the bullet is believed to be, and when it strikes the ball a galvanic battery is formed within the body This will cause a click to be heard in the telephone each time the bullet is struck This is a far simpler apparatus than the induction balance, and one far more easily procured and it would be well if surgeons called upon to treat gunshot wounds would test its practical utility Professor Graham Bell s efforts to apply electricity to surgery are most praiseworthy, and the results he has obtained merit the attention of surgeons

Possibly several workers carried out Graham Bell s suggestion For my own part, I saw immediately that this was a method which ought to be tried at the first opportunity, and a suitable case presented itself at the Aberdeen Royal Infirmary in 1887 A woman had been shot in the face by a revolver, and the bullet had gone into the antrum and had caused a good deal of destruction of bone The arrangement which I made for Dr Ogilvie Will, who performed the operation, consisted in the first place of a silver plate 6 in long and 4 in wide which was placed upon the patient s skin the skin being freely moistened with salt solution in order to make it as good a conductor as possible This plate was then connected to one terminal of the ordinary Bell telephone, and the other terminal was attached to a silver probe thus carrying out Bell s condition as to metals of the same nature On introducing the probe into the entrance wound no sound was heard until a considerable depth had been reached, when a distinct rattle became audible characteristic of contact with the metal, and the bullet was extracted without any difficulty Some years later a London Hospital physician, who was bringing me cases at a time when I was using the telephone probe to verify the results of early X ray localisations learned the use of this instrument, and subsequently showed it to Sir Frederick Treves, who used it, greatly to his satisfaction, in the South African War More particularly it enabled him to differentiate, as neither the common probe nor the finger could do, between a distorted and broken up Mauser bullet and a fragment of bone[2]

Until quite recently I took it for granted that the condition laid down by Graham Bell—namely, that the instruments used for exploration must be of the same metal as the plate placed upon the patient s skin—was essential to the success of the method It is only since the outbreak of the present war while assisting at various operations and noticing the considerable difficulty experienced by surgeons in finding the bullets, even after the most precise X ray localisation, that I began to experiment again with the telephone, with the result that I have now extended its applicability to any metallic instrument to which the surgeon chooses to attach it

THE PHYSICS OF THE TELEPHONE

Before describing in detail the procedure I recommend, which has been tried successfully in a number of cases, I should like to make a few preliminary remarks about the physical questions involved in the construction of the telephone, since a clear understanding on this point is necessary to an intelligent appreciation of the use of the telephone as a surgical instrument With the use of the telephone in ordinary life everyone is familiar, but perhaps I may be pardoned for reminding my colleagues of the nature of its construction and the principles upon which it acts The Graham Bell telephone consists of a permanent magnet, around one pole of which is a helix or coil of very fine insulated wire The fineness of the wire and the number of its turns decide the resistance of the telephone, and, incidentally, affect its cost If the currents for which it is to be used are very small while the voltage or electrical pressure is high, the number of turns in the coil must be correspondingly large On the other hand if the voltage is very small there should be fewer turns, and these of thicker wire, so that the resistance may not be too great The action of the telephone depends upon variable currents passing through the coil, which cause variations in the magnetic strength and lead to the attraction and release of a small, thin iron disc placed in front of the magnet This vibratory action of the disc results in the emission of sound waves. It is by far the most sensitive instrument for the detection, by sound, of the feeblest intermittent currents but it gives no sound during the steady passage through it of a continuous current This fact has the most practical bearing on the method of using the telephone in surgery, as I shall hope to demonstrate shortly

When two dissimilar metals are separated by an electrolyte they form the elements of an ordinary primary battery, and wires attached to them, on being joined together, convey an electric current The pressure or voltage depends upon several factors, but generally it can be stated that the difference of potential between various metals rarely exceeds two volts Until recently I entertained the idea that if dissimilar metals were attached to the terminals of the telephone the moment that these metals touched the human body the latter would act as an electrolyte and a click would be heard in the telephone, which might

Unfortunately, if the lodged foreign body is of non magnetic metal, such as shot, for example, unless it is visible in the anterior part of the eye, its extraction is impossible, and the eye in consequence is lost. It might be well worth attempting the removal of such bodies with the telephone attachment, because a very distinct sound is produced in the telephone on contact with the minutest metal particle Indeed, particles so small as to be almost invisible would be quite appreciably audible The ideal procedure would be to have the foreign body precisely localised by means of X rays, as is being constantly done at Moorfields and other eye hospitals, and then to attempt its removal with the aid of the telephone I am afraid, however, that this method will not be of much assistance in cases where the foreign body is lodged in the vitreous and not firmly attached to the coats of the eyeball From experiments with the eyes of dead animals I find that a small shot, placed in the vitreous cavity, is not easily detected by means of a needle with the telephone attachment It has already been made plain that the whole success of this method depends upon an actual momentary contact with the metallic foreign body The vitreous is of so yielding a nature that the small foreign body is pushed away in front of the needle, and this intervening layer of vitreous prevents a good metallic contact from being made Should the foreign body happen to be between the needle and the fundus, then it can be readily heard, and of course if it is embedded in the coats of the eye there is no difficulty whatever in obtaining the usual sound on impact with the exploring needle In spite of the difficulty with the vitreous, I would suggest that, before enucleating an eye containing a non magnetic foreign body, the ophthalmic surgeon should first attempt the removal of the foreign body with the telephone attachment

CASES

Comparatively recently I have had two cases of small pieces of shell in the orbit The first of these was brought to me by Mr Cruise The case had been radiographed by Captain Howard Humphris, of the 3rd London (Wandsworth) Military Hospital, and the fragment was indicated at the upper and inner part of the left orbit Mr Cruise asked me to let him try the telephone for its removal At that time I had not ascertained that carbon was the best element to place upon the patient s skin, and I used a piece of platinum foil which I had in an old Grove s battery This was bandaged on a skin thoroughly moistened with salt solution (the position is of no consequence), and a long needle was placed in a holder and fixed to the other end of the telephone The patient having been anæsthetised Mr Cruise, with the double telephone at his ears introduced the needle in the direction indicated by the radiographs and at some considerable depth he heard the microphonic rattle Sir A Pearce Gould who was present on this occasion, held the needle in position while Mr Cruise cut down along it through a comparatively small incision The telephone was then attached to the forceps the rattle again being distinctly heard and the foreign body was removed immediately afterwards he whole operation being carried out with the least possible disturbance I think such a case very well illustrates the advantage which the surgeon gains by trusting to his hearing instead of making a large wound and retracting its walls and depending upon his finger and his sight for the detection of the foreign body

The next case, also in connexion with the orbit, was one in which Mr Armour removed a piece of shell which had entered the head above the right eye and had gone through into the left orbit, where it lodged Here again Mr Armour ran down a needle attached to the telephone, and heard the sound on contact with the foreign body before he made any incision Mr Herbert Menzies assisted him at this operation The foreign body was successfully removed, and the patient, whose eye is now normal, has had no subsequent trouble

The same arrangement has now been used successfully in quite a number of cases The latest of these may be cited, since it is especially interesting owing to the fact that the flattened casing of a German bullet was deeply embedded in the lumbar region of a very large and muscular man. The depth of the bullet in the tissues was between 3 and 4 inches, and Mr English, who successfully removed it after it had previously been localised very accurately by means of X rays, ran a long needle down on to it, and heard the contact through the telephone before making an incision He found the telephone most useful throughout the operation, which was made more expeditious in consequence

In view of these cases I would take the liberty of suggesting that the surgeon, now that the telephone is available, should go to the trouble of altering somewhat his technique Instead of trusting to his sense of touch through his rubber gloved fingers he should trust to his sense of hearing, and guided by this it ought to be possible for him not only to find the foreign body but to free it from its surrounding entanglements With the aid of the telephone he can always keep in touch with its boundaries, whatever the surgical instrument he may be using at the time, and finally, by means of his forceps he should be able to remove it through a comparatively small incision and with the least possible disturbance of the parts This necessarily implies some preliminary practice and, what seems to be still more difficult, some alteration of habits long since acquired The special value at the present moment of such a procedure as the use of the telephone, in view of the large numbers of operations which are necessary in cases returned from the seat of war, needs no insistence, and I believe that the time will come when no surgeon will attempt to remove a deeply embedded metallic body without having this telephone attachment at his command

MODIFICATIONS

Of the modifications which might be proposed in the general arrangement the most obvious is the introduction of a small dry cell into the circuit I have not found, however, any marked advantage to accrue, and on the ground of absolute simplicity the method as already described seems to be preferable At the same time the battery experiment is easily tried, with the small dry cells now used for hand lamps, and quite portable One objection to the battery is that if it is interposed the sound produced on contact of the instrument with the tissues is heard very distinctly, and it seems to me that with the battery there is a great risk of stray and misleading sounds occurring in the telephone In view of the fact also that one might be in districts where a battery was not available it seems better to keep to the arrangement outlined above especially now that the carbon plate is employed which is practically indestructible and requires no attention or renewals impair the value of the method for the subsequent detection of a bullet by contact On making the experiment, however, I found that this effect was in no way prejudicial It is true that a slight sound is sometimes heard when the instrument first comes in contact with the tissues, but not even the least experienced person could confuse it with the sound produced on contact with the embedded bullet or other metal

I have tried many pairs of ordinary metals in order to discover which would yield the best result The metals for which we have to search most frequently are lead, nickel, copper, iron, and some of the iron alloys used in shell manufacture The surgeon's metallic instruments are usually steel, silver, or nickel plated With any of these instruments attached to one terminal of the telephone I find that on contact with any of the above mentioned embedded metals the loudest sound is elicited when a plate of carbon, such as is used in an ordinary bichromate cell, is attached to the other pole and placed, in the manner described at the beginning, upon the moistened skin of the patient The result may be still further improved if a fine layer of iodine is interposed between the skin and the carbon plate, this is readily done by brushing the skin with the usual iodine solution employed as a disinfecting agent

The currents generated in these circumstances are, of course, small in amount, and of low pressure It is important, therefore, to reduce the resistance of the body as much as possible, and on this account it is necessary to use on the skin a plate of carbon of as large a size as is convenient, and to increase the conductivity of the skin by moistening it well with the usual salt solution. The resistance of the human body is high, varying from 3000 ohms through the skin when dry, down to 300 when the skin is moistened, and it appeared likely, as has proved to be the case, that the cheap telephones of low resistance would be best suited to detect these small currents A telephone of 60 ohms resistance, costing only a few shillings, gives a louder sound than the more expensive high resistance telephones used in wireless telegraphy I have here two telephones of 40 ohms resistance, and I am investigating as to how far the resistance may be lowered in order to obtain the most distinctive sound

THE SURGICAL PROCEDURE

Briefly put, the method I advocate for adoption is the use of a telephone, preferably with double receivers, connected together by means of a steel or elastic band, so that each ear has its separate receiver This not only increases the intensity of the sound, but also serves to cut off extraneous sounds which might interfere with the audibleness of the telephone Should the surgeon wish to have one ear uncovered so as to be able to attend to the remarks of anyone near him, it is quite a simple matter to move aside one of the receivers This double arrangement, however, is not essential, and a single telephone gives quite good results if the surgeon's hearing is acute The carbon plate is placed upon the patient's moistened skin, and plaster or bandage may be used for holding it in position tightly against the skin The other end of the telephone should have attached to it a bare wire, of silver preferably, which has been disinfected, by boiling or otherwise as the surgeon may direct One end of this wire being attached to the telephone terminal, which of course cannot be disinfected readily, the other end need be handled only by the surgeon or his assistant with the usual antiseptic precautions, and the wire can either be wound round any instrument it is desired to use or, as I have demonstrated this evening, a spring clip may be employed by means of which the wire can be conveniently brought into connexion with the knife, probe, needle, or forceps, as the case may be

Under these conditions, if the instrument is introduced into the body it will, on first contact with any metal, give rise to an unmistakeable click carried through the telephone, and then, if it be gently moved or slightly disturbed so as to make a rubbing contact with the foreign body, an equally unmistakeable loud rattle will be elicited By such means the metal can be dissected out (if the knife is used), or otherwise freed from the encircling tissues, because a constant control can be exercised over the foreign body by reason of the microphonic rattle it produces when the instrument comes into contact with it A very useful point to bear in mind is that in cases where a foreign body has been carefully localised by means of X rays a needle can be attached to the telephone in the manner stated, run down on to the foreign body, and, when the characteristic sound is heard, can be maintained in its position as a guide before any incision is made

The telephone attachment to forceps is particularly useful, because these can be used as a probe, and then, when opened to include the foreign body this action gives a characteristic sound which betokens when the foreign body is between the jaws I had a pair of bullet forceps made some time ago which were thoroughly insulated outside with vulcanite, the bare metal only remaining on the inner side of the jaws This modification has the advantage that the sound can only be heard when the bullet is actually between the jaws, otherwise an equal sound, and a quite misleading one, would be heard if the forceps were not grasping the bullet but were only touching it on their outer side

It is obvious that the surgeon must be careful when the telephone is attached to his instrument not to allow that instrument to touch any other metallic instrument which may be already in the wound, such as a retractor or artery forceps, because, of course, this will make an audible impression in the same way as the embedded metal itself As a rule, this is not difficult to avoid, but should he be exploring a narrow and deep wound where there is any difficulty in preventing possible contact with his instruments I would recommend him to place a rubber drainage tube over his exploring instrument, except in the neighbourhood of its point In this way he will conveniently insulate it from any of the surgical instruments which it might encounter along the walls of the wound Another simple plan is to cover the needle or probe with a thin layer of shellac, by heating and applying the shellac in the same way as with an electrolysis needle when the action is desired to be confined to the point By such means the bulk of one's instrument may be insulated

UTILITY IN OPHTHALMIC SURGERY

The telephone arrangement seems to me to have a special utility in ophthalmic surgery For many years ophthalmic surgeons have successfully extracted very small pieces of iron or steel from the eyeball by means of a powerful electro magnet

Syphilitic splenomegaly with anæmia appears to be due to congenital syphilis, and may persist despite antisyphilitic treatment, including the administration of salvarsan In the few cases I have seen recorded there is no mention of hæmorrhages occurring

My own experience of splenectomy for enlarged spleen with anæmia comprises three cases which I now describe, they were all referred to me from the medical wards by my colleague, Sir Robert Simon Two other cases with enlarged spleen are present for your examination So far neither of them is the subject of anæmia, but we hope to keep them under observation that we may learn what their future will be, especially as to whether at a later date they will develop anæmia and the other changes sometimes associated with it

CASE 1. *Banti's disease, splenomegaly anæmia, hæmatemesis, melæna, ascites, splenectomy*—The patient aged 19 was admitted to the General Hospital under Sir Robert Simon on June 19th, 1913, complaining of pain in the abdomen and of passing blood by the bowel. The patient was fairly well nourished but looked very anæmic and ill, the temperature was 101° F and the pulse 128 The past history showed that for about six years he had complained at times of aching pain in the upper abdomen generally coming on some time after a meal and relieved by the taking of food. The pain was not constant, it lasted only a few minutes as a rule, vomiting did not occur, and there were often intervals of freedom from pain which might last weeks Four days before admission when getting out of bed he suddenly felt very weak and could hardly get up He experienced no pain but stayed in bed all day, and noticed that the bowel action was dark red in colour, this continued until the patient came to hospital. On the night of admission he vomited 10 oz. of bright-red clotted blood, and this hæmatemesis with the past history suggested at first duodenal ulcer

The spleen was found to be enlarged, it extended inwards to the linea alba, it felt hard and rather uneven, but was not tender The only other point needing mention was the presence of soft bruits systolic in time heard over all the heart valves Bleeding from the bowel continued for three days and was treated by the administration of horse serum The blood examination on June 25th showed red cells 1,800 000, white cells 10,000, and hæmoglobin 20 per cent On July 8th the figures were—red cells 1 900 000 white cells 7500 and hæmoglobin 30 per cent On the 11th it was noted that the abdomen was becoming distended and the surface veins prominent On the 14th distension of the abdomen was more marked and the patient's colour did not improve On the 19th distension was marked and there was much fluid in the abdomen. The pulse ranged from 120 to 96 but very rarely was less than 108 The temperature varied from 98° to 101° but was usually from 99° to 100°, the respirations were from 24 to 36 The urine rarely exceeded 30 oz., its specific gravity was rather low but it contained no abnormal constituent

I saw the patient on several occasions with Sir Robert Simon and we arrived at the conclusion that he was suffering from Banti's disease Operation was discussed but postponed in the hope that as there were no fresh hæmorrhages the general condition would improve This hope was, however not fulfilled, on the contrary a large and increasing ascites developed and we felt that the prospect of a successful operative interference was diminishing rather than increasing and the patient was therefore submitted to operation on July 21st

Operation—The incision commenced in the middle of the epigastrium high up and extended outwards below and parallel to the left costal margin then down the linea semilunaris to the level of the umbilicus A large quantity of pale yellow slightly turbid fluid estimated at several pints escaped from the peritoneal cavity, this fluid appeared to be paler and thinner than the ordinary fluid of ascites due to cirrhosis of the liver The spleen was very carefully drawn out through the extensive incision it was fortunately found to be free from adhesions The pedicle contained enormous vessels all of which were free from thrombosis, and in the wall of the pedicle were numerous small masses of tissue which were evidently splenculi It was determined to tie the pedicle in sections with silk, when this had been partly accomplished some of the vessels tore owing to the weight of the organ The remainder of the pedicle was therefore clamped, the spleen cut away, and the vessels unsecured were tied individually, and finally a ligature was tied round the whole stump of the pedicle so that it was absolutely dry The liver was quite free from cirrhosis, and no thrombosis of vessels was recognised, but owing to the patient's feeble condition it was impossible to make any systematic investigation on this point The abdominal incision was closed, and whilst this was being effected 1½ pints of normal saline were transfused into one of the veins of the arm, as collapse was rather marked

The spleen with its contained blood weighed 4 lb, it was somewhat harder than a normal spleen and was practically free from perisplenitis Examination of the ascitic fluid showed that it had a specific gravity of 1011, its reaction was alkaline, it contained a heavy cloud of albumin, and was free from sugar from urea, and from blood Microscopically a few small round and oval cells were found

On the day following the operation the patient had completely recovered from the shock, and at the end of a week he looked decidedly better, the pulse was then generally below 100 The blood count was red cells 2 700 000, white cells 12 500, and hæmoglobin 50 per cent After this time improvement was slow, the pulse again quickened, and was often as high as 120 and over About the middle of August there was considerable abdominal pain, vomiting occurred several times and occasionally diarrhœa, a good deal of ascitic fluid was present, and the boy looked thin and anæmic. Soon after this he was sent to the Jaffray Hospital and on Sept 8th was allowed to get up, his pulse, however, was still quick generally 110 or higher, but he gained 3 lb in weight in eight days Becoming discontented he left the hospital on Sept 25th, and was lost sight of until recently

Subsequent condition—The patient was examined on Dec 9th, 1913 He had gained weight and felt well except that he tired easily It was thought that a little free fluid existed in the abdomen The red count was 4 000,000 hæmoglobin 40 per cent. and leucocytes 16,000 In May, 1914, the red count was 4 000 000 and white cells 12,000 The abdomen appears to be free from fluid and the patient is at work as a railway porter He occasionally has slight epistaxis

CASE 2—Male, aged 20 Shop assistant Admitted under Sir Robert Simon Feb 9th, 1914 Complaint on admission, jaundice four months ago, since which he had been confined to bed with intermittent pain in the left flank The patient stated that previous to this time his health had been good Father, mother, six brothers and three sisters are in good health

The present illness commenced in the middle of October, 1913 with an attack of jaundice lasting about three weeks Since this time he had felt weak though not very ill When admitted he was found to be muscular but distinctly thin, the face was pale and sallow, but there was no actual jaundice The temperature was 101° F., pulse 120, and respirations 24 The teeth were very bad, many molars missing and the incisors of the upper jaw decayed, the tongue was clean but rather dry The abdomen was relaxed, there was no pain or tenderness The spleen was found to be greatly enlarged, it reached downwards to the mid Poupart line and 2 inches to the right of the middle line of the abdomen The liver was somewhat enlarged, its lower border was felt 2 inches below the costal margin Heart, faint mitral systolic murmur No notable condition in the respiratory system Blood examination showed red cells 2 700 000 and white cells 2800 On Feb 12th the red cells were 1 010 000 white cells 2200 and hæmoglobin 50 per cent, on the 14th the figures were 1 587 500, 2000, and 60 per cent respectively On the 19th it was thought that the spleen was somewhat smaller and as there was a little expectoration this was examined for tubercle bacilli but none were found From time to time there seemed to be some slight variation in the size of the spleen The blood count on May 3rd showed—red cells 2 600 000 white cells 5900, and hæmoglobin 50 per cent The patient's condition was not satisfactory He looked ill was markedly anæmic and appeared to be losing weight His temperature was 103° or more at

Several attempts have been made over a number of years to apply electricity in some form to this surgical purpose The idea of using electricity for the detection of bullets embedded in tissues has been traced back to 1862, when a method was brought forward, apparently with no great success, by Professor Favre, of Marseilles Ten years later a civil engineer, named de Wilde, proposed the use of an electric bell as the signal for the presence of a metallic body in the tissues In the case of President Garfield, as I stated at the beginning of this paper, the induction balance was employed, this last I do not look upon as a practical method of locating bullets, all that it does being simply to reveal their presence The telephone, I believe, will be found the most simple and reliable method for aiding the surgeon in the removal of a bullet previously localised by means of X rays

If something other than the sound of a telephone were required—for instance, in the case of a deaf surgeon—it could be obtained by a modification of the method I have been advocating Instead of taking the current through the telephone it could be passed through a suitably wound galvanometer and the movement of the galvanometer needle would then indicate contact with the metal, or this arrangement could work as a relay and a bell would ring every time the bullet was touched by the surgeon's implements It seems to me, however, that these are less practical than the simple plan advocated in this paper, and I have every confidence in recommending it to the attention of the surgeon

SPLENECTOMY FOR ENLARGED SPLEENS WITH ANÆMIA[1]

BY GILBERT BARLING, M B LOND, F R.C S ENG,

SURGEON, BIRMINGHAM GENERAL HOSPITAL.

AT the risk of being regarded as elementary I would like in the first instance to recall to your minds very briefly something of the physiology of the spleen It has in part, as you will remember, a very slow blood current owing to the terminal arrangement of some of its arteries, which do not end in capillaries but in dilated spaces in the splenic pulp In this slow current the leucocytes pick up the damaged and worn out red corpuscles, digest them, break up their colouring matter, and with part of it produce some, at all events, of the colouring matter of the bile Beyond this main function it is probable that the spleen takes some part in the destruction of infections, again through the leucocytes in its meshes, and it may have a hormonal function which to some extent controls pancreatic secretion

For many years past the spleen has occasionally been removed for various conditions, for displacement with or without rotation of its pedicle, for cystic disease, for traumatisms, or for what has been called simple hypertrophy This last condition probably was an early stage of the splenic enlargement with anæmia, which we now operate on under the name of Banti's disease, acholuric jaundice, &c However that may be splenectomy for the conditions I have mentioned above proved to be a reasonably safe procedure and fully justified Unfortunately the ardour of some surgeons led them to remove the enlarged spleen for leukæmia with ghastly results I do not know a well authenticated case in which the patient recovered, and happily we are all agreed that the operation in leukæmia is quite unjustifiable Experience of splenectomy has shown that a patient whose spleen has been removed may live a perfectly normal life under *ordinary* conditions and that the expectation of life is not shortened The assertion has been made that therefore a patient is no worse off without a spleen than with one, but this seems to me hardly justified at present This may not be true if the patient is involved in a struggle for existence against an infection—pneumonic, typhoidal, pyogenetic, or similar poison—when the whole forces of the body may be necessary to carry the fight to a successful issue The only case I am acquainted with bearing on this point is one mentioned by French,[2] the patient a boy aged 6, survived both measles and scarlet fever after splenectomy It would be interesting to know if in other cases recovery has occurred after similar illnesses In the absence of the spleen other organs appear to carry out its work—the lymphatic glands, the bone marrow, and the liver

Under the title "enlarged spleen with anæmia," which I have taken as my subject, several conditions are grouped together, in all of them we find enlarged spleen, marked reduction in the number of red corpuscles and in hæmoglobin, with either some degree of leukopenia, a normal leucocyte count, or one that is somewhat increased The enlargement of the organ and the diminution in the red corpuscles appear to be due to great exaggeration of the chief normal function of the spleen This exaggerated function may be excited in different ways, in one case by the poison of syphilis, in kala azar and in malaria by the particular parasites associated with these diseases, perhaps in other cases a streptothrix as suggested by Gibson[3] may be the stimulation Further investigation is not unlikely to reveal other provocative agents of a similar kind

I said just now that under the title "enlarged spleen with anæmia' various conditions are described having certain common features Then comes divergence, and further knowledge is required to determine whether we have to deal with really different diseases provoked for instance by different forms of infection, or merely with accidental divergences due to the different reaction of individual patients tissues Under the names Banti's disease, acholuric jaundice hæmolytic jaundice, and syphilitic splenomegaly we find grouped most of the splenomegalies with anæmia at all events in this country Banti's disease implies in addition to enlarged spleen and anæmia a marked tendency to hæmorrhages chiefly from the gastro intestinal tract, ascites, and in some cases cirrhosis of the liver or thrombosis of some part of the portal system I propose to show you a typical example

Acholuric jaundice has additional features which the name implies, jaundice with an absence of bile in the urine The jaundice appears very early in life and has been described as congenital, there is in addition an unusual fragility of the red corpuscles, but this may entirely disappear after splenectomy

Hæmolytic jaundice resembles in many respects acholuric jaundice but the jaundice does not appear until, it may be, some years after birth The urine is deeply coloured but may not contain the ordinary bile pigments, the red corpuscles are unduly fragile, and cholecystitis with or without gall stones may occur

---

[1] A lecture to a post graduate class at the Birmingham General Hospital

[2] Proceedings of the Royal Society of Medicine vol vii No 5, Clinical Section p 77

[3] Quarterly Journal of Medicine January 19[illegible] vol viii, No [illegible]

CASE 5—A male aged 37, was admitted under me on May 1st 1914, complaining of pain in the left side of the abdomen, duration six weeks The father and mother are healthy, 2 sisters and 4 brothers alive and healthy The patient is a moderate drinker and smoker No previous illnesses but he has occasionally suffered from epistaxis while bending over a basin washing himself The patient attributes his present condition to straining himself while at work six weeks ago, when he did three days of extra heavy work, following this he had severe pain in his left side There has been no vomiting of blood nor melæna

Condition on admission—A healthy looking man, complains of no pain at present nor of discomfort Temperature and pulse normal Abdomen On palpation the spleen is found to be markedly enlarged, extending downwards almost to the umbilicus It is of firm consistence but the edge is not well marked except at the lower part, it is not tender Liver not enlarged Urine normal Wassermann reaction negative Blood examinations on three consecutive days white cells 16,000 15 000 and 15,000, red cells, 4 400,000 4,200 000, and 4,300 000, and hæmoglobin, 80 per cent

The patient was discharged, but was made an out-patient to be kept under observation

In conclusion, may I remind you that the first case is a typical Banti's disease, the second is probably of the same nature, though we have positive evidence of a definite infection, tubercle As to the third, in which the patient died with an acute hepatitis after operation, the hæmorrhages suggest she too may have been an early example of this type Cases 4 and 5 both have considerably enlarged spleens without blood changes, and their future course will be watched with interest Case 5 was seen in December, 1914, when he appeared to be in good health, he had, however, found a lighter occupation The splenic enlargement had not altered, no opportunity offered of examining his blood At present it is impossible to determine the meaning of the splenomegaly of which they are the subjects

Birmingham

A CRITICAL STUDY OF THE BASIS OF ABDERHALDEN'S SERUM REACTION

BY W E BULLOCK, M D EDIN,

IMPERIAL CANCER RESEARCH FUND

THE great mass of literature dealing with the subject of this paper has been reviewed so recently by Abderhalden,[1] by Lange[2] and others that it is unnecessary here to do more than to refer to special points and to emphasise the division of opinion as to the value of the reaction in the diagnosis of pregnancy and of disease On the one hand, numerous writers[3] support Abderhalden's results and conclusions completely, one observer declared it to be possible to distinguish between a gastric and a duodenal ulcer[4] On the other hand a few writers[5] on the subject totally deny the existence of specific protective ferments Between these extremes there are some who partially confirm Abderhalden's work, and others who corroborate the experimental results but offer another explanation of them[6]

The chief object of the work to be described was to test the reliability of the reaction as applied to the diagnosis of cancer But before carrying out the routine empirical tests devised by Abderhalden the experimental results on which the whole method is based were examined The experimental results claimed are briefly 1 By injecting animals with solutions of sucrose maltose or other sugars strange to the economy of the animal employed protective ferments are developed in the body which decompose the strange sugars and render them useful or at least innocuous to the animal. The evidence adduced that such ferments are produced is as follows The blood serum of the normal animal is mixed with a solution of the sugar to be injected and the mixture examined with the polariscope, no alteration in the rotatory power of the solution takes place When now the blood serum is obtained after the animal has received an injection of the sugar and is mixed with the sugar solution as before, the rotatory power of the solution gradually changes, indicating a splitting up of the sugar 2 When an animal is injected with a foreign protein a similar phenomenon is said to be observed Ferments are produced which are able to break up the protein into peptones and amino acids, acting in this way in a protective capacity The optical method was again employed, in this case allowing the blood serum to act upon solutions of peptones prepared from the protein used to inoculate the animal

These are the essential experimental results, and they are extended by speculation and reasoning by analogy to practical ends In the case of pregnancy, for example, it is said that since cells of the placental villi may break off and pass into the maternal blood stream, and as these cells are made up of proteins strange to the mother, protective ferments may be produced But pregnancy may be diagnosed very early (in the first month) by the method, and it is obvious that the total weight of placental cells which may in this time get into the maternal blood stream is excessively small, it is, therefore, unreasonable to assume that this process can be solely responsible for the production of the protective ferments Further, in some animals—e g, the mare—the relationship of the placenta to the mother precludes the possibility of cells of the villi escaping into the blood stream Hence a long theory, based on endless assumptions, of the relationship between the maternal and fœtal metabolism is elaborated to show how protective ferments may be produced in the mother by simple products of the fœtal metabolism.

By a similar process of reasoning the experimental results already mentioned have been made a basis for researches on practically every subject within the scope of medical science It is all the more important, therefore, to repeat and consider carefully the experiments by which the existence of specific protective ferments is considered to have been established

The optical method of demonstrating the ferments does not, on the surface, appear to be very satisfactory In the first place, the maximum rotations observed by Abderhalden are very small, in fact, only just outside the limits of error of the polariscope employed In the second place, blood serum is chemically such a complex liquid that small changes in its optical activity are not necessarily significant In this connexion it should be observed that Abderhalden states that blood serum may be kept indefinitely at 37 C without any alteration in its optical activity, and it will be shown later that this statement comes into direct conflict with evidence obtained by the dialysis method For these and other reasons the fundamental experiments with sugar as the substrate have not been repeated In the last number but one of the *Journal of Biological Chemistry* Hogan has published a paper on the parenteral utilisation of disaccharides in which he comes to the conclusion that his data 'yield no evidence whatever night, the pulse varied from 112 to 128, and the respirations were generally 24 There was no evidence of free fluid in the abdomen

Splenectomy was determined upon and was carried out on March 9th An incision was made in the left semilunar line, and this was prolonged upwards, the seventh and eighth costal cartilages near the bony ribs being divided, thus giving considerable addition to the operating space The abdominal cavity was free from fluid, there was much perisplenitis, and fibrous adhesions above attached the spleen to the under surface of the diaphragm and to the posterior abdominal wall These adhesions were divided, several vessels were tied here, and the rest of the oozing was stopped by packing, whilst the splenic pedicle was ligatured in detail The liver looked quite healthy except for a localised patch of perihepatitis on the upper surface of the right lobe, this area was not as large as the palm The abdomen was closed, the divided rib cartilages being sutured with catgut The spleen was found to weigh 3 lb 5 oz There was moderate shock, as the operation had been rather prolonged owing to the time spent in dividing the adhesions mentioned above, but half an hour after the operation the patient's condition was quite satisfactory

The wound healed per primam, and at first it seemed as though the patient were going to make a complete and satisfactory recovery The temperature fell to normal and remained so for five days, it then slowly began to rise again, and eventually returned almost to its old level, being on an average one degree lower than before the operation The blood counts after operation were as follows —

	Red cells	White cells	Hæmoglobin
March 12th, 1914	2 260,000	8 000	50%
,, 14th, ,,	2 250 000	7 000	60%
,, 26th, ,,	3 200 000	7,000	90%
,, 31st, ,,	3 690,000	7,800	90%

On April 24th a number of carious teeth were extracted as the patient was not doing well, and it was thought wise to extirpate any possible infective focus During the next few days he was losing condition, complained of discomfort in the abdomen, he had bronchitis on both sides of the chest, and he looked thinner and more ill The abdomen began to swell, the legs became œdematous, the eyelids puffy, and there were some slight petechial spots observed The patient's relatives getting discontented with his want of improvement took him home on May 16th At that time he had a large ascitic collection, his legs were swollen, his temperature was about 103° at night, his pulse, always quick, ranged from 110 to 120, and he looked as though he were steadily losing ground [I am unable to trace the patient — G B]

The immediate improvement after splenectomy gave ground for believing that speedy restoration to health would ensue, the subsequent relapse was therefore the more disappointing The improvement in temperature following operation suggested that the extirpation of the spleen had removed the great source of infection The subsequent rise came on very gradually, and eventually the evening rise was as great as before the operation

CASE 3 —A girl aged 6 was admitted under Sir Robert Simon on Jan 21st 1914 with a history that on the day previously she had vomited a pint of brownish fluid mixed with blood clots Six weeks before the child had had a severe hæmatemesis, she vomited several times at school and three times after she reached home The previous history showed that she had been under treatment for four years for paralysis of the left arm which had practically recovered Scarlet fever and measles with bronchitis had attacked her in the first 18 months of life The spleen was enlarged and quite mobile, its upper border reached to about three inches below the left costal arch Blood examination showed red cells 3 300 000, white cells 26 000 and hæmoglobin 70 per cent Further examination showed about the same amount of red cells and a diminishing white blood count, which eventually was as low as 7000 Later the white blood count rose to 18 000 the red cells being then 3 600 000 and the hæmoglobin 60 per cent A general examination of the cavities revealed no other evidence of disease

On Feb 25th the child was remitted to me for splenectomy, with the diagnosis of early Banti's disease Incision was made in the left semilunar line The spleen was very sessile to the stomach, and there were some adhesions below the pedicle, but these were easily ligatured piece by piece, and the operation of removal was a comparatively easy one. It was noted at the time that the liver presented an absolutely healthy appearance, it was perfectly smooth, its capsule was not thickened, and its colour was typical of a healthy liver, there was no ascitic fluid Shock was moderately severe and saline was given by the rectum with speedy improvement The pulse however, remained persistently quick, it had been about 100 before the operation Immediately afterwards it was 176, it, however, dropped to below 120 There was persistent vomiting at first, and the patient was very restless On the third day after the operation the pulse had quickened up to 160–180, the respirations were over 40 the temperature was as high as 105° F for some hours, and the child died the next day

The necropsy showed a satisfactory condition of the wound area, there was no peritonitis, and the only condition found to explain death was the state of the liver, the naked eye appearance of which suggested delayed anæsthetic poisoning The anæsthetic given was a mixture of ether and chloroform The note of the examination of the liver by Dr Logie, visiting pathologist, is as follows —

Macroscopically the liver was enlarged and pale, its surface smooth and glossy It cut easily and appeared to be in a state of acute hepatitis with cloudy degeneration On microscopical examination the portal tracts showed well marked cellular increase and in many cases marked proliferation of bile ducts The intralobular capillaries were dilated and well filled with blood The vessels generally were engorged and there were some small hæmorrhages The parenchyma showed atrophy of the liver cells which were opaque more or less necrotic, and all in a state of fatty degeneration The nuclei were obscured and stained badly The cells in the neighbourhood of the portal tracts showed some fatty infiltration Those more remote were degenerate and in some parts quite destroyed

Dr A G Gibson has been kind enough to examine the spleens removed from these patients and in one of them, the organ from Case 2, tubercle bacilli were found, in the other two cases no infective organisms were recognised *At the operation on Case 2 no tuberculous condition was recognised in the abdominal cavity, and the question arises whether the primary condition in the spleen was one of tubercle or whether this was superimposed on some pre existing change*

CASE 4 —A male aged 12 was admitted on April 25th, 1914, under Sir Robert Simon, complaining of pain in his ankles The patient is one of a family of ten, of whom three died in infancy, the mother has had two miscarriages The other members of the family are all healthy except one boy, aged 15, who is always rather pale and whose feet are "flat" The patient has had no previous illnesses Three years ago last March he complained that the right foot was painful His mother states that this condition first came on after the boy had been kicking a ball about The foot was rested, but the pain continued and he has never been able to use his foot since He had his foot put up in a plaster of Paris case 15 months ago and this case he wore for ten weeks Six weeks ago his left foot also became painful and since then he has not been able to use either foot For the last fortnight his ankles have been tender and swollen

Condition on admission —A well nourished and fairly intelligent boy unable to walk but can lie in bed comfortably Both feet show well marked pes planus There is considerable œdema of both ankles Abdomen Full and rather flat, the spleen is large and palpable as low down as the umbilicus, a distinct notch can be felt The liver is not palpable There is a soft systolic murmur at the apex of the heart, this is not propagated towards the axilla. The murmur can also be heard to the left side of the sternum the pulmonary second sound sharp and rather accentuated Lungs normal Two blood counts at intervals of a few days gave the following results red cells 6 400 000 and 5 200 000, white cells 9600 and 8500 and hæmoglobin 90 per cent

The condition of the ankles improved under treatment and the patient was discharged as an out patient so that the condition of his spleen and his blood might be kept under observation of the inoculated rabbits gave the precipitin reaction against solutions of egg white, and in the three cases tested anaphylactic shock was induced

It will be noticed that in the tests with serum alone a positive ninhydrin reaction, progressively stronger with increasing doses of serum, is obtained This result may be due either to the presence of amino acids in normal rabbit blood or to a production of these substances by an autolytic enzyme Abderhalden has demonstrated that amino acids in minute amounts are normally present in blood serum[10] Working with very large quantities of blood—e g, 50–100 litres—he was able to isolate glycocoll, alanin, prolin, leucin, &c, but owing to the energetic chemical methods employed there is a possibility that the amino acids obtained were produced by the reagents used in the process The question was therefore investigated by a new and simple method

20 c c of blood were drawn from a rabbit's ear vein and rapidly centrifuged in order to obtain clear serum The serum was pipetted off into a strong large sterile test-tube, which was immediately immersed in boiling water and kept there for 20 minutes in order to inactivate any enzymes which may be present and to kill any organisms which may have contaminated the serum The serum clotted, and a clear watery fluid separated This fluid was pipetted off into sterile test-tubes, and again heated and then placed in two sacs and dialysed for 18 hours against 20 c.c of distilled water in the usual way The dialysates reacted faintly with ninhydrin and were negative to sulphosalicylic acid, it was therefore concluded that blood serum does normally contain amino-acids The experiment was repeated twice with rabbit's serum and with dog s serum with the same results

In order to determine whether the blood content of amino acids is increased during digestion an experiment was carried out in which rabbits which had fasted for 24 hours, and rabbits which had received a meal of oats and green stuff within three hours of the experiment, were bled and equal volumes of the serum obtained were treated in the manner already indicated. The dialysate from the fasting animal's blood serum gave a slightly fainter tint than the other dialysate, and from this result it is probable, considering the quantities of serum used, that any increase in the amino acid content of the blood after a meal is too small to be detected in 2 c c of serum. It is possible, of course, that in an animal like the rabbit, with a great length of intestine and a large cæcum almost invariably loaded with partially digested food, the difference between a fasting animal and one in a state of digestion is very small It was very noticeable that the dialysate from the serum of the animal in a state of digestion gave a temporary red colour when boiled with ninhydrin, this being due, probably, to glucose

A further experiment was made to determine the influence of a previous bleeding

An animal was bled and the serum obtained was sterilised as before and the clear watery fluid pipetted off, and after being heated placed in the ice chest Four hours later the animal was again bled and the same volume of serum obtained and heated in the water bath The clear watery fluid was pipetted off heated cooled in the ice chest and 5 c c placed in a dialysis sac and dialysed against 20 c c. of distilled water In the same way 5 c c of the watery fluid from the first bleeding was dialysed against 20 c.c. of distilled water After 18 hours the dialysates were tested with ninhydrin and the reaction obtained with the dialysate from the serum of the second bleeding was much deeper than the other

It may be concluded that amino acids are washed from the tissues by the fluids which flow into the vascular system after a bleeding These results do not preclude the possibility of a ferment action taking place in normal unheated blood serum Indeed, it was observed that the depth of the ninhydrin reactions with fluid from 10 c c of serum was not more than equal to that usually obtained in an ordinary experiment with 1 c c of serum In order to test for an enzyme action the following experiments were made

An animal was bled aseptically at least 30 c c of blood being taken, the blood immediately centrifuged, and the clear, watery, hæmoglobin free serum was pipetted off into a sterile test tube Into each of half a dozen or more sterile dialysis sacs 2 c c of blood serum was placed, and the sacs dialysed at different temperatures for 18 hours against distilled water The temperatures chosen were as nearly as possible as follows 5° (in chest), 20°, 30°, 40°, 50°, and 60° C It was not always possible to set the baths at exactly these temperatures, but practically the temperatures employed were round about those stated The baths used maintain the temperatures at which they are set to within half a degree during the 18 hours of the experiment

The dialysates were tested in the usual way with ninhydrin, and the tints obtained gradually increased up to 40° C and then diminished at the higher temperatures The maximum was, in every experiment but one, round about 40° C The results were compared by the method of dilution already described,[9] and the dilution numbers plotted against the temperatures as shown in the curves below The following are examples of the experiments —

1 A dog was bled and the serum obtained by centrifugalisation In order to be quite certain of the sterility of the serum it was filtered through a Berkefeld filter The accompanying experiment was carried out (Table IV) The curve for the dilution numbers is given in Fig 1 From this experiment, in which in addition to using toluene every precaution was taken to exclude organisms, it is clear that an autolytic enzyme has been active

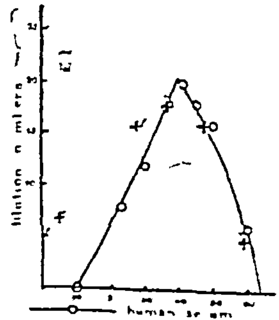
S S A test = sulphosalicylic acid test

FIG 1



The dotted line shows the gradation in the depth of the ninhydrin reaction obtained with dog serum incubated at different temperatures The dilution numbers give the volume of water added to 1 c c to bring the tint of the liquid to the degree of faintness of the weakest reaction

2 The curve (Fig 2) for the dialysis of a solution of peptone was obtained by dissolving 0 4 g of Witte's peptone in 20 c c of distilled water, and dialysing at different

that any enzyme or any useful protective factor hitherto described is regularly developed in the animal body by the parenteral introduction of lactose or sucrose "

Turning now to the part of the experimental work in which albumins are used as the substrate, it is essential first to refer to the dialysis method which was employed to demonstrate the ferments The technique adopted has been described in a previous paper[5] In order, however, to prevent any misunderstanding it is necessary to emphasise several parts of the process In the first place asepticity was observed throughout The dialysis sacs, elongated Petri dishes, and pipettes were sterilised in the autoclave and used immediately they were cool The substrate was sterilised before use by boiling for several minutes in distilled water, the blood was drawn off aseptically into sterile centrifuge tubes, and after centrifuging the blood serum was pipetted off into fresh sterile tubes The contents of the dialysis sacs and the distilled water in which they were placed were both covered with a layer of pure toluene In testing the dialysate with ninhydrin 10 c c of the liquid, to which 0 2 c c of 1 per cent ninhydrin solution had been added, was boiled over the Bunsen flame for one minute

It is essential, according to Abderhalden, to use antigen and blood serum free of every trace of hæmoglobin. In experimental work with animals it is easy to obtain hæmoglobin free serum In order to do this the blood is collected quickly and centrifuged at 6000 revolutions per minute before coagulation occurs The serum obtained is almost colourless and quite free of hæmoglobin If the blood is allowed to coagulate before being centrifuged it is necessary to break up the clot, otherwise the serum will be mixed with fibrin in which red blood corpuscles are entangled With human blood it is more difficult to obtain serum which is quite free of hæmoglobin owing to the fact that, as a rule, at least several hours elapse before the blood is centrifuged The process by which the substrate may be obtained free of blood is fully described by Abderhalden in his book "Die Abwehrfermente "

Lange[2] states that in his experience the presence of hæmoglobin in the blood serum or in the substrate has no influence on the result of the reaction, and this opinion has been confirmed in the course of this work by numerous experiments For example, a human placenta was taken and divided into two parts, one of which was washed free of blood and prepared according to Abderhalden s directions, the other being boiled at once Two ecimens of placental substrate were thus ob ed, the one white and free of hæmoglobin, the other dark brown owing to the presence of altered blood Blood was now obtained from a woman in labour and the experiment described in Table I carried out.

TABLE I

Sac	Serum	Substrate	Ninhydrin test.	Sulphosalicylic acid test.
80	0·5 c.c.	HbO free placenta.	–	–
81	1·0 ,		–	–

70	0 5 ,	Bloody placenta	–	–
83	1·0		–	–
75	1 5		+	–

The reverse experiment, in which hæmoglobin free blood serum is obtained and divided into two parts, hæmoglobin being added to one part and both now incubated with and without placenta, was also performed In this case also the presence of hæmoglobin exerted no influence on the reaction. Similar results were obtained with the blood and various substrates of the dog and rabbit These experiments, though of the nature of preliminary investigations, were not carried out until a considerable proportion of the work described in this paper had been completed Consequently in all the experiments to be described it is to be assumed that, unless stated to the contrary, the blood serum and substrate were hæmoglobin free

Aberhalden's experiments, on which the whole theory of protective ferments is based, were repeated in the following manner

Half a dozen large healthy rabbits were taken, and the blood serum of each animal was allowed to act on coagulated egg albumin The result of each experiment was negative, as the accompanying example shows (Table II)

TABLE II

Sac.	Serum.	Saline	Substrate	Ninhydrin test	Sulpho-salicylic acid test.

77	2·0 ,	0	,	++	(?)

Thus the serum is without action on coagulated egg white Following Abderhalden s method of procedure the rabbits were now injected intravenously (the second injection two days after the first, and the third one day after the second) three times with egg albumin diluted with normal saline The dose administered on each occasion was 2 c c of a 50 per cent solution of albumin The rabbits were bled as follows 2 on the fourth day, 2 on the fifth and 2 on the sixth day after the last injection The sera obtained were tested against coagulated egg white and in each case the result was negative The accompanying table (No III) is typical —

A similar series of experiments was carried out, inoculating other sets of rabbits subcutaneously and intraperitoneally, and with the same results In no case was any evidence obtained of the production of a protective ferment The blood serum dialysable ninhydrin reacting substances than the serum of the dog, the rabbit, the guinea pig, or rat

These results enable one to conclude that an autolytic ferment exists in the blood serum of rabbits, dogs, and human beings, and that it is responsible for some of the amino acids indicated by the ninhydrin test It does not follow, however that it is impossible to diagnose pregnancy by Abderhalden's method This requires to be tested directly, and for this purpose it was determined to use animal material owing to the ease with which blood serum can be obtained and male controls set up Rabbits and dogs were tested Blood was obtained from female animals both during the early days of pregnancy and immediately before or during delivery In every case blood serum from a male was used as control Altogether over 20 tests were made, and the results obtained were concordant and invariably negative, as the following examples illustrate

A pregnant rabbit and a buck were starved 18 hours and then bled The serum was filtered through unglazed porcelain and the following tests made (Table IX) —

Similar experiments, in which, however, the blood serum was not filtered, gave the same result An example of a test with dog serum and dog placenta has already been given

The difficulty of obtaining blood serum from human patients for the purpose of experimental work is very great, and renders it practically impossible to test the method as thoroughly as has been done for animals It was however, essential to make some experiments, and this was rendered possible by the kindness of Dr Kettle of St Mary's Hospital, who procured four samples of blood obtained during delivery As a control to these tests in one experiment the blood serum of a healthy adult male was used. In each test (including that with serum from male) it was found that the ninhydrin reaction of the dialysates of serum plus placenta was deeper than in the case of the dialysates from serum alone The results here are therefore quite different from those already detailed above The serum (from male and female) does break down placenta protein or in some way liberate amino acids But since this result had already been obtained in connexion with tests in cases of cancer in animals to be described later, it was decided, in spite of the small number of cases examined, not to continue the work

The following example is typical Blood obtained during labour was centrifuged and the serum, yellow in colour but free of hæmoglobin, was pipetted off (Table X)

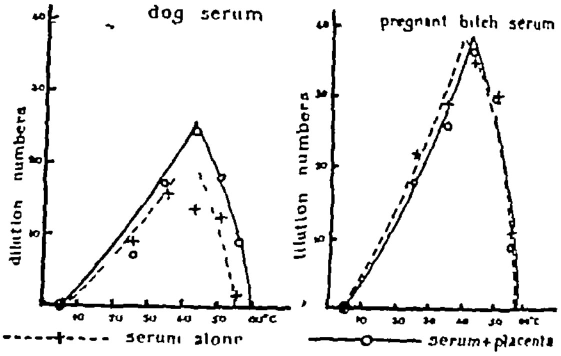
It will be noticed from the curves (Fig 3) that (1) There is no evidence of digestion of the substrate either by the serum from the pregnant bitch or by that from the dog, (2) the serum from the bitch yielded a greater amount of amino acids than that from the dog, and (3) the curve for dog serum alone is distinctly more irregular and rises to a smaller height than the curve for dog serum plus placenta This is due to the fact, as has been shown in the previous paper,[9] that sacs 117, 116, 113, and 115 were made at a later date than the sacs used in the rest of the experiments (except sac 112), and had been autoclaved fewer times In connexion with (2) above, it may be stated that my colleague, Dr Compton, estimated the content in the ferment maltase of both these sera and found a difference corresponding to that noted above In view of the findings of Bertrand and Compton[11] the agreement between the maltase and proteolytic ferments in the two lots of serum is of considerable interest

FIG 3



Showing that no degradation of placental tissue occurs either with dog or with pregnant bitch serum

4 Blood serum of rabbits was examined in the same way with similar results A normal Belgian hare was starved for 26 hours and then bled, the blood was centrifuged and the clear, hæmoglobin free serum pipetted off The serum was divided into two parts to one of which 0 5 c c of hæmolysed red blood corpuscles was added The sera were now filtered through separate Berkefeld candles and the following experiment carried out (Table VII)

It was not possible to obtain dilution numbers The optimum temperature is here about 30° C

5 About 40 c c of blood was drawn from the median cephalic vein of a healthy man (B R G R) and hæmoglobin free yellowish serum obtained This was dialysed in lots of 2 c c against water at different temperatures for 18 hours (Table VIII) Fig 1 shows the curve The double dose of ninhydrin is required owing to the fact that human serum yields do c for dose, a smaller amount of

ELECTROTHERAPY AT A BASE HOSPITAL

BY W J TURRELL, M A., M D OXON,
CAPTAIN, R.A.M C (T F) THIRD SOUTHERN GENERAL HOSPITAL
ELECTROTHERAPEUTIC PHYSICIAN RADCLIFFE
INFIRMARY OXFORD

VERY little attention has hitherto been drawn to the value of electrotherapy in the treatment of the sick and wounded in war time The only published references to this subject of which I am aware occur in a paper, "Le Service de Physiotherapie de l'Hôpital Militaire du Dey a Alger," by Dr Hertz, Medecin Major de 1re Classe[1] and in a paper entitled "La Physiotherapie des Blesses de Guerre," by M Miramond de Laroquette[2] Both these papers are concerned with the work at the military base hospital at Dey in Algeria, where a department of physiotherapy had been established to meet the needs of the wounded soldiers during the war in Morocco Before reaching this department the primary lesions of the soldiers had been cured, and the department was solely concerned with the secondary troubles, often very severe, such as paresis and paralysis following on nerve lesions, 16, ankylosis or articular stiffness, 43, functional incapacity or atrophy, 3, total, 62

In the 41 cases in which a definite result was obtained there was a complete cure in 51 per cent, marked improvement in 24 per cent, and no result in 24 per cent Of the remaining cases 8 were invalided out of the service and 3 were placed on half pay The writers claim that without the aid of physiotherapy the number of those permanently disabled and in receipt of State pensions would undoubtedly have been much increased. The methods employed were, in the cases of neuritis and wasting, the continuous current of high intensity with long seances, and sometimes in addition a current of rhythmically interrupted galvanism For the arthritic lesions radiant heat and mechanotherapy were used The chronic effusions were treated by radiotherapy, in pastille doses, every fortnight

At the Radcliffe Infirmary, which forms one of the subsidiary hospitals attached to the Third Southern General Hospital, a very complete electrical installation has recently been added The installation comprises Nagelschmidt s diathermy apparatus with a high frequency attachment, a powerful American Baker 8 16 plate static machine, a Bergonie apparatus for obtaining electrically provoked exercises, a 500 candle power leucodescent lamp for radiant heat, an electric light bath of 48 incandescent and four arc lamps a Kromeyer mercury vapour quartz lamp, two pantostats, and batteries, &c, for rhythmically interrupted and reversed currents

Of the 78 cases which have already been electrically treated 31 have been cases of frost bite Of these 24 have been discharged cured and 7 remain under treatment (See Table) It is not suggested that these cures would not have occurred under other forms of treatment or perhaps without any treatment, or even in spite of treatment But it is claimed that by adopting electrical methods the most acute pain is speedily relieved, the stasis and swelling of the affected parts are reduced, the vitality of the tissues is increased, and in the necrotic cases the tissues are kept dry and aseptic whilst separation is hastened by the increased hyperaemia which follows the application of the treatment.

In frost bite cases the form of electrical treatment is selected on the following principles If the pain is very severe diathermy is found to give the best results When the pain is very acute the treatment is commenced as soon as possible after the patient s arrival at the hospital, and in the more severe cases two treatments are given daily In cases of slight frost bite electrical treatment is not usually given, any slight pain which may exist usually subsiding with one or two days' rest and warmth, occasionally, however, cases with no pain on admission develop a neuritis of the feet requiring electrical treatment a few days after admission Cases which have lost sensation to heat are not suitable for diathermy, as there is a risk of the heat blistering them

Table showing the Number of Patients Treated, the Methods of Treatment adopted, and the Results to the Middle of January

Nature of complaint and number of cases		Method of treatment					Result

The following are the notes on a case in which diathermy was given in consequence of the pain disturbing the patient's sleep —

CASE 1 —The patient was admitted on Dec 17th, 1914 Was frost-bitten about the end of November, whilst on active service in the trenches He stayed in the trenches till Dec 11th, when he was unable to endure the pain in his feet and reported sick The pain had continued every night, disturbing his sleep On the night of Dec. 18th there was considerable pain Dec 19th Diathermy 10 by 5 c m electrodes 0 9 ampère, for 10 minutes yesterday There has been no pain since treatment and the patient had good night Dec 20th Diathermy repeated on the 19th There is now no pain in the feet. The patient can walk well and is recommended for sick furlough

Captain C A Coventon has kindly supplied me with the following notes of two of his cases which were treated by diathermy for severe pain in the feet following frost bite

CASE 2 —The patient was admitted on Dec 31st, 1914 Frost bite in both feet, very painful preventing sleep On Jan 1st 1915, he was admitted to Radcliffe Infirmary for electrical treatment On the 5th there was much less pain he slept well and there was more movement On the 6th he continued to improve, was now quite well, and was discharged to sick furlough The electrical treatment in this case seemed to cause immediate improvement the pain ceased, and convalescence went on uninterruptedly

4 A guinea pig tumour was washed free of hæmoglobin until the tissue was white, and was then extracted with chloroform to remove the large amount of fat usually found in this tumour The product was then boiled in distilled water acidified with acetic acid, and again in distilled water until the water failed to react with ninhydrin A guinea pig bearing a tumour and a normal guinea pig were bled from the heart and sera obtained The animals were not previously starved (Table XIV) In this experiment the reverse of what was shown in the last experiment is obtained, the serum of the normal animal produced a greater ninhydrin reaction than the tumour serum but again in both sets of tests there is an indication of a degradation of tumour protein or of some physical action liberating amino-acids

Up to the present it has not been possible to obtain materials necessary to carry out similar experiments in cases of cancer in the human subject

Results and Conclusions

1 It was found impossible to cause the production in rabbits of a ferment which digests coagulated egg white by the injection subcutaneously, intraperitoneally, or intravenously of raw egg white

2 A minute quantity of amino acids is present in 10 c c of blood serum of rabbits and dogs, and it was found (in rabbits) that after a bleeding these substances are increased in amount

3 An autolytic ferment is found in the blood serum of rabbits, dogs, and in human serum

4 The serum of the pregnant rabbit is unable to break down rabbit placenta, and the serum of the pregnant bitch is unable to break down dog placenta Human blood serum from the pregnant female and from the healthy male, incubated with human placenta, produced by chemical or physical action amino acids

5 Rat blood serum ("normal" and "tumour") breaks down rat tumour (J R S A Rat 9) Guinea pig serum ("normal" and "tumour") breaks down guinea pig tumour and mouse tumour 63 The blood serum of the guinea pig was not rendered more active in this property by a previous inoculation of the animal with mouse tumour 63

The method devised by Abderhalden, even with the technical improvements described, is thus seen to be inadequate to distinguish normal from pregnant or cancerous sera The fundamental experiments adduced by Abderhalden do not, on repetition, give the results stated by him, and a proteolytic ferment normally present in the serum of mammals acting on tissue substrates of varying lability, prepared in accordance with his directions in all probability accounts for his results and their confirmation by others

by electrically provoked exercise to the back (positive) and seat and thighs (negative) After the treatment the patient walked back to the ward by leaning on his wheeled chair, on the following day he walked to the electrical department with the aid of sticks, and after a repetition of the exercises he walked without assistance On the third day the Morton wave current was applied to the back to clear up any remaining stiffness No further treatment was required, and the patient was discharged on sick furlough

Oxford

FEAR AND DISEASE

BY E T JENSEN, M B LOND, M R C S, L R C P,
PHYSICIAN TO THE SPECIAL HOSPITAL FOR OFFICERS KENSINGTON PALACE GREEN

TOXIN formation and the physical effect of toxins on the organism have been investigated both bacteriologically and dietetically as the cause of alimentary toxæmia, but we are still searching for that fundamental factor which allows the toxins to enter the blood in excessive quantities I wish in this paper to put forward a hypothesis showing that this fundamental factor is, either partly or entirely, the direct result of a mental state Dr E Mellanby raises this question when he says[1] —

> The key to the situation is not held by a consideration of the bacteria of the intestine, nor of the chemical end products of bacterial action but rather by knowledge as to the normal methods of intestinal absorption and more particularly of *the mechanism which prevents the passage of toxic substances across the mucous membrane* into the blood stream [Italics are mine] The important question is What is the cause in acute intestinal disturbance which brings about the breakdown of the defensive mechanism and allows the entry into the blood stream of toxic substances ?

Dr Murray Leslie seems to emphasise the same question when he says[2] —

> It seems to me that sufficient stress has not been laid by previous speakers on the first factor—namely the power of resistance on the part of the individual. It is true that reference has been made more than once to the fact that there is no necessary relationship between the amount of stasis and the degree of toxæmia. It is a matter of daily clinical observation that some persons can remain constipated for days and even weeks without apparently suffering any ill effects while in other instances the missing of the usual after breakfast evacuation is invariably followed by headache malaise, and inability for physical or mental exertion Habit-tolerance, important though it may be does not altogether account for such phenomena. There seem undoubtedly to be individual idiosyncrasies in respect of liability or resistance to toxæmia. The importance of the personal factor is exemplified by the well-known liability to bacterial invasion (including bacillus coli infection) of persons debilitated by injury disease, over fatigue senile tissue degeneration and other conditions leading to diminished vital resistance Thus for instance, it is known that shortly before death when the vital protective forces are more or less in abeyance, the bacillus coli and other bacteria can freely pass through the intestinal mucous membrane and so into the circulation while their toxins not being neutralised or destroyed, accumulate in the circulating blood and are no doubt responsible for many of the symptoms preceding dissolution including ante mortem pyrexia. Metchnikoff indeed believes that such absorption is the primary cause of death in most cases of senility while any check to such absorption tends greatly to prolong life

I am led to believe that in some of these cases at least nervous worry and all the emotions of an unpleasant character which I summarise generically as fear are frequently a direct cause of alimentary toxæmia Under the heading of "fear I group broadly all such emotions as may contain an element of fear, such as anxiety, sorrow (a present loss, with fear of unhappiness in the future), over work, anger (fear of another), exaggerated self consciousness (fear of criticism), and pain, with its milder varieties of malaise and fatigue Fear, in its generally accepted sense, or any excitement of an intense and unplesant nature, will commonly result in pallor with a feeling of faintness, while gastro-intestinal and vesical disturbances frequently ensue

What are the physical causes of these effects and, if these causes persist, how is the organims affected ? Compare the physical signs of fear with the results of shock During abdominal operations shock effects are sometimes manifest and have often been described Here the intestines become deeply injected, increase in volume, and may finally emerge from the body cavity This distension is not due to the formation of gas, it is paralytic The vaso constrictor fibres of the splanchnic area are paralysed, and similarly those whose function is to maintain visceral tone The face becomes pallid from the fact of the blood leaving the head to fill the vessels of the mesenteric area, blood pressure is lowered, and if shock is severe or continued the heart may stop Short of this last, the following conditions, by reason of this dilatation, then obtain (1) The absorption area of the inner intestinal surface is greatly increased, (2) the absorbing area of the blood vessel wall is also increased, (3) the intestinal wall is thinned, (4) the walls of the blood vessels are thinned, (5) they contain more blood, and (6) the blood stream is slowed, remaining longer in the absorption locality Now we have on the one side of the intestinal wall blood (and lymph), and on the other side food and toxins All these six factors tend, by the law of osmosis, to favour absorption of the intestinal contents into the blood Is it not therefore probable that the same condition, to lesser degree but for longer duration is induced by the shocks and resultant fear complexes incidental to most lives ? Truly more food may at the same time be absorbed, but prematurely, in that case, further increasing the waste products to be afterwards eliminated In any event, the toxin rather than the food question here holds the field.

I submit that the effect of fear will produce to some extent the same condition of intestinal collapse observed in surgical shock, slight possibly in degree, but sustained if the cause persists, and further that this loss of visceral tone tends, in the erect posture, to cause a drag on the visceral nerves (which cannot stretch as much as the gastric and intestinal muscles) and enhances the shock effect We note that in order to diminish this factor and lessen the heart s work the subject prefers to lie down.

A patient describes how the sight of an accident affects his stomach He develops wind immediately and his heart becomes embarrassed He has an all gone ' sensation in his abdomen Here again one can only believe that a sudden paralysis of gastric and probably of intestinal muscular fibres allows the expansion of gases already present, and that dilated viscera now press on the heart As the emotion passes the tone of his intestinal tract returns, and the expulsion of wind from the stomach often completes his recovery A man bracing himself for an ordeal instinctively tightens his belt (girds up his loins) He feels a vague need of abdominal tone and has a sense of power (courage) when this manœuvre has been carried out Atony and flatulence may, I believe, be

[2] Ibid p 27

CASE 3 —Frost-bite in both feet The patient was admitted on Dec 31st, 1914, with great pain necessitating morphia, there was no great discolouration and very slight movement On Jan. 3rd, 1915, he was admitted to Radcliffe Infirmary for treatment by Captain Turrell On the 5th the pain was much less, he slept through the night, and had much more movement in the toes On the 12th he continued to improve On the 14th he was discharged to sick furlough The remarks on the improvement of the other case equally apply to this one

The so called cases of trench pain or trench feet usually have no tissue destruction, no blebs, and not even any discolouration of the skin, they would appear to be due to acute neuritis of the feet excited by cold and exposure The most acutely painful case we have treated was of this nature The day after admission the patient was writhing in bed with agonising pain, his hands clenched, his face buried in the pillows, his face and feet covered with perspiration, there were no physical signs of any lesion This patient was the only one we have treated who derived little or no benefit from diathermy, on the third day of his treatment the diathermy apparatus was temporarily out of order, so he was treated by the static breeze instead He was immediately relieved, slept the whole of that night, and only had a slight recurrence of pain on the following day and this was relieved by a repetition of the treatment The patient had no further relapse, and two days afterwards was walking about the ward The other patients who have been treated by both methods have always stated that their pain has been more relieved by the diathermy than by the static This patient was suffering from considerable nervous exhaustion, and probably a great part of the benefit he derived from the static breeze was due to the constitutional effect of this treatment

Cases with no ulceration, but with blebs, and cases with loss of sensation to heat, we find respond best to the high frequency vacuum tube It is remarkable how quickly the blebs dry up under this form of treatment Where there is ulceration and necrosis the static breeze with the patient negatively charged is the best form of treatment The worst case of frost bite which has been admitted to the hospital has been under treatment for about six weeks by this method On admission the toes were hard, dry, and withered, the sole of the foot was covered by a large black bleb, on the dorsum of the foot a line of demarcation was already appearing about one inch from the base of the toes The static breeze has been applied daily, and pain, whenever it has occurred, has been relieved by the treatment The toes are now separating at the metatarso phalangeal articulation The granulations are very healthy in appearance, the wound has kept perfectly aseptic, and only on one occasion has the temperature risen to 99° F The patient's general health has much improved The œdema and induration on the dorsum of the foot have nearly disappeared

The rationale of the static breeze in the treatment of frost bite is apparent from the following description by Dr Benham Snow of the therapeutic action of this modality "The effect upon local stasis   where swelling and induration are present is to generally soften the tissues This is due to the action of the discharges producing recurrent contractions of the tissues, thereby inducing an onward movement of the blood current through the vessels Over superficial œdema and where ecchymosis is present the effect of these applications systematically applied is remarkable in its results   To ulcerated surfaces the application of these modalities is one of the most valuable in therapeutics Applied over the indurated margin, where it has a positive effect in relieving stasis, it proves to be of the greatest value for the relief of those conditions The circulation is restored throughout the zone of induration, which surrounds the ulcer, when a reparative process is immediately instituted '[3]

Several patients have been treated on account of very severe pain in the extremities following crushing or partial division of a nerve It has been found that diathermy has always afforded marked relief, after the first treatment the pain is usually absent for four or five hours and subsequent treatments result in a longer period of relief In treating patients with very severe pain two applications of diathermy are administered daily, the second one being given as late as possible in the evening Treated in this way patients who previously had only experienced brief relief from hypodermics of morphia sleep through the night without pain Diathermy does not appear materially to shorten the period of convalescence in these cases, nor does it prevent the occurrence of trophic changes in the skin In order to keep the patient free from pain the treatment has to be continued in some cases for two or three months Often when the treatment is omitted for one day the patients complain that they have missed it and have had more pain

In cases of nerve degeneration, if the mischief is slight, and the muscles react to faradism, the rhythmically reversed faradic current is used Where the faradic reaction is lost, when there is no pain associated with the lesion, rhythmically reversed galvanism is used, when pain exists rhythmically interrupted galvanism is selected For testing electrical reactions the condenser method is used and is found to be not only much quicker, but also to give more information in regard to the degree of nerve degeneration than the faradic and galvanic methods

Sprains of muscles and synovitis of joints usually yield readily to the Morton wave static current, and the patient's stay in hospital is generally materially shortened by this treatment The Morton wave current, either alone or in association with ionic medication, is used for the treatment of stiff joints

The following interesting case of "spinal concussion" speedily yielded to the persuasive influence of Bergonié's machine for electrically provoked exercises The rapid cure will probably be attributed to electrical suggestion, but in view of the vigour and amplitude of the muscular contractions excited by this apparatus "electrical demonstration" might be a better term

CASE 4 —The patient, whilst serving at the front was driving an ammunition wagon when a shell exploded under the wagon, killing one horse and severely wounding the other The patient states that he was blown several feet into the air, and on falling dragged himself to the shelter of a hedge where he remained all night The following morning he could neither walk nor stand On being taken to the medical officer the patient states that pins were pushed into both his legs without producing any sensation On admission to the Third Southern General Hospital the patient appeared to be unable to draw up or move his legs or to stand up The reflexes, sensation and electrical reactions were normal. After a few days' rest in bed the patient could walk a few steps with assistance, he was then transferred to the Radcliffe Infirmary for electrical treatment He was there treated directed to the restoration of this tone has seemed to cut the vicious circle, presumably by allowing purer blood to repair damaged tissue or organs which by their inefficiency have shown themselves to constitute weak points. Particularly prominent are cases in which the nervous organisation has broken down and where I believe the fear, acting through the splanchnic nerves, has paralysed the intestine, causing absorption of toxins into the blood. This toxæmia affects the nerves, intensifying the symptoms and possibly establishing and confirming a fear complex, while at the same time it impairs the vitality and contractile power of the visceral muscle. I will not attempt to apportion the improvement in these cases between the renewal of the patient's confidence and the arrest of toxic absorption. The two coöperate. Synchronising with this improvement increase of tone often becomes evident in a firmly contracted or contractile colon being now palpable instead of a gurgling unresponsive one, while the abdominal wall, once flabby or rigid and tender, has become supple and elastic. Prominence of gaseous distension has disappeared, and the abdominal muscles now exercise their function of holding the viscera back in position.

---

[3] Benham Snow High Potential and High Frequency Currents

Loss of tone in voluntary muscles has been noted by various authorities, and Professor Geddes draws particular attention to the slackness in these cases of the abdominal muscles. This seems naturally to follow the general loss of control shown in all asthenic conditions, particularly noted in neurasthenia and psychasthenia. In this connexion the effect of continuous fear—i.e., worry—is easily explainable. Worry is a succession of fear states causing a loss of tone which becomes chronic. Further than this, we have to take into consideration the gradual establishment of a general affect tone, built up from successive experiences of a like nature. As the process of worry continues, the worry habit is formed and experiences of a neutral tone are coloured by the general outlook of the patient, converted into definite asthenic affects which aid the lowering effect on the mental energy, and lead to further loss of tone and the establishment of a psycho physical vicious circle. In the development of atony in the alimentary tract (leading to visceroptosis) the fear or worry factor has often been a long time active before definite physical effects become evident. It follows, then, that the most rapid and efficient course is not always to direct the treatment to the physical condition alone, but to try at the same time to cut the psycho physical vicious circle in another place by attacking it on the psychic as well as on the physical planes and so to ease that tension of the mind which tends to keep up the condition of atony with its toxic sequelæ.

Thus, to summarise, apart from the consideration of the eliminating capacity, which may here be assumed to be more or less constant for the individual toxæmia from the alimentary tract has always two factors—the chemical, comprising the toxins themselves, and the vital dealing with the resisting power of the individual. This resisting power depends, I believe, on tone of the viscera and is powerfully influenced by the subject's state of mind. Further, this tone may well be part of a condition which should be normally shared by the entire musculature of the body. This explains incidentally, I think, why the active are, as a class, more healthy than the sedentary.

I add a corollary to the foregoing. If fear can paralyse the hollow viscera, it must follow that happiness and courage can, to some extent at least, cause them to contract and check toxic absorption. This would constitute a link between mind and body by which the power of suggestion is transmitted to the organism. Thus may some of the cures by Christian and allied "sciences" be explained, and improvement in health follow improvement in circumstances, be these affairs of heart or pocket.

Medical Societies.

ROYAL SOCIETY OF MEDICINE

SECTION FOR THE STUDY OF DISEASE IN CHILDREN

Exhibition of Cases and Specimens

A MEETING of this section was held on Jan 22nd, Mr T H KELLOCK the President, being in the chair.

Dr F D SANER showed a case of Congenital Syphilis in a girl. The child was apparently quite healthy until just over two years ago when she had some pain and stiffness in the left elbow and ankle-joint. Some months later a small hard lump appeared about the centre of the forehead which gradually enlarged and finally ulcerated. The left leg became very deformed and for nine months before admission the child was unable to walk. No specific treatment had been given until the child was admitted to hospital on Nov 11th 1914. She was then extremely wasted and anæmic, and did not eat or sleep. There was a large circular foul smelling ulcer with a sloughy base in the centre of the forehead quite half as large again as the present condition. The eyes were almost closed from œdema of the upper lids. The liver and spleen were distinctly palpable. Wassermann's reaction was positive. Since admission hyd c. creta 1 gr had been given three times a day and an inunction of ung hydrarg ¼ dr once daily. In addition pot iod. 5 gr c inf. gentian co ad 2 dr, t.d.s had been given, and sanitas fomentations to the forehead. A hydrogen peroxide mouth wash had been used, and the treatment had been very well borne. The child had gained 12 lb in weight since admission, and her general condition was satisfactory.

Dr H W BARBER and Dr F D SANER showed a case of Enlarged Liver in a boy, admitted to hospital on Dec 27th 1914, for pain in the right side, which had only been present for a few days. The boy was of average development for his age and there was no history of any previous illnesses. On examination the liver was considerably enlarged, on the right side its lower border nearly reached the iliac crest, in the mid line its lower margin was just below the umbilicus and it could be traced to the left costal margin at the level of the ninth costal cartilage. The spleen was not enlarged. The Wassermann reaction was positive. There was no eosinophilia.

Mr SYDNEY STEPHENSON reported a case of Hæmatoma of the Lower Lid (an unusual manifestation of infantile scurvy). A female infant aged 5 months, was brought to hospital on Jan 7th. She had been well until the middle of last December when she developed "thrush," diarrhœa and vomiting symptoms from which she made a fair recovery in the course of about a fortnight. On Jan 3rd a small black spot or line was noticed in the skin of the right lower eyelid. There had been no injury to the parts. On the following morning the eyelid was swollen and discoloured. For the first two months of life the baby had been breast fed and after that Swiss milk was given exclusively. Since recovery from the attack of December last nothing had been given in the way of food except albumin water. No patent foods had been used in bringing up the infant. On admission the right eye was completely closed by the pressure of the lower lid which was enormously distended with blood. The swollen parts were almost chocolate-brown in colour. The upper eyelid was not swollen and exhibited merely a few insignificant patches of cutaneous ecchymosis. The eyeball was not protruded. The cornea was clear. The temperature was 99° F. The child had some colour in her mutually dependent on one another, and the presence of a gas producing micro organism favours absorption of visceral content by causing stretching and thinning of the gastric and intestinal walls I deem it likely that flatulence can directly cause constipation, a lacuna of gas in an over distended section of gut producing a block in the peristaltic wave

Dryness of the mouth is another symptom of fear which is due, I suggest, to a general re absorption of fluid from the tissues in a compensatory endeavour to help to fill the vascular area, which has become enlarged owing to splanchnic paralysis, and thus to restore the vital equilibrium by raising the lowered blood pressure The disappearance of thirst after a saline injection for shock illustrates the effect of our artifice in the supplying of material to assist a natural process The evacuation symptom, which frequently results from fear, may be due to a falling of fæces, on paralysis of the previously emptied and contracted pelvic colon and rectum, to the point in the rectum where the evacuation reflex is obtained Should the ileo cæcal valve not be exempt from this suggested paralysis the small intestine, pouring liquid chyme into the colon, could give rise to the diarrhœa which is so often noted A micturition reflex from fear may be explained in the same way The sphincter is relaxed and escaping urine stimulates the reflex point in the posterior part of the urethra followed by urgent contraction of the bladder

A nursing woman is said to produce toxic milk after an outburst of anger or receiving a fright This circumstance would be difficult to account for otherwise than on some absorption theory like the above, and I suggest that abortion and miscarriage brought on by fear may be attributed to spasmodic uterine contraction (preceded possibly by an emotional paralysis of the os uteri, analogous to that suggested as affecting intestine and sphincter vesicæ) induced by toxic blood circulating in the uterine vessels or in the central nervous system

Sea sickness, it is well known, may be favoured and sometimes caused prematurely by fear[3] In other cases I think it likely that the movement of the waves gives rise to shock with gastro intestinal paralysis and toxæmia Perhaps the vitiated blood stimulates the vomiting centre in the medulla Dilated viscera now press on a heart already hampered by low blood pressure, until some temporary relief is obtained by vomiting or eructation. The practice of tightly binding the abdomen and the success as prophylactic of pituitary extract, which raises blood pressure and causes intestinal contraction, appear to support this view Causes originating in the eye or semicircular canals could initiate the same sequence of events

I believe that slow convalescence after any infective illness is, partly at any rate, due to delay in the recovery of visceral tone Many a patient can, with precision, date his improvement from the moment when he made a resolution to get well On the contrary, it is generally accepted that nervous people are much more liable to the diseases and disasters they fear than are those whose courage is at a high level These results would seem to follow naturally, if we can accept the theory that fear induces atony with resulting toxæmia Nervousness sufficient to elicit a blush contains a small element of fear, and here a vasomotor paralysis alone is effected while the gastro intestinal tract escapes After shock prolonged for a considerable time it is likely that the "defensive mechanism will suffer and that absorption will become habitual on the establishment of the vicious circle For even when the fear is removed or diminished, the stomach and intestine, long fed by vitiated blood, may not at once recover their tone if the absorption of waste products has been overbalancing the eliminating capacity Also the stomach tends to remain dilated and the colon to become the seat of accumulations consisting of fæces, possibly hardened, and mucus (which latter sometimes becomes organised into fibrous tissue) with sandy deposits of urates or phosphates Now all these factors prevent the restoration of colonic tone and peristalsis and induce constipation If, however, obvious constipation does not result the liquid content of the small intestine, propelled by the *vis a tergo*, can pass easily through a furred colon (to borrow a simile from a water pipe) in which circumferential layers of fæces move more and more slowly the nearer they lie to the wall of the colon till, at their periphery, stasis to a variable extent will obtain Diarrhœa may characterise this condition

The reason why some constipated persons are not obviously poisoned is, I believe, because (1) they are generally young and may have become constipated through habit and dietetic error, though other causes are not excluded, (2) their eliminating apparatus and toxin destroying agents, working at high pressure, are still efficient, and (3) they have not yet lost intestinal tone, having no fear or anxiety state Given time, their intestinal stasis aided or not by fear, will eventually impair the tone of the hollow viscera and toxæmia will result Tone is partly independent of peristalsis, though loss of the one may influence the other In how many cases are people over 40 with constipation well?

So far I have mainly considered the circular muscular fibres of the hollow viscera. If these can be paralysed by fear, so, we may reasonably presume can the longitudinal fibres and bands The effect of this will be to lengthen the stomach and intestine, and, with the paralysis of the circular fibres, to increase their entire capacity in every dimension Lengthening a hollow viscus, which is securely fixed at certain points, must infallibly produce sagging between those points, and this factor I consider at least as important as a prime cause of visceroptosis as that attributed by Sir Arbuthnot Lane to the weight of a loaded colon only An atonic colon would become sooner and more heavily loaded than one tonically contracted Thus ptosis would not be caused by, but would cause stasis Surgeons have noted a collapsed state of the appendix sometimes occurring when this organ is inflamed Such an appendix would more readily admit and retain accumulations than one active in peristalsis and tone

Mr Lockhart Mummery describes a case which seems to bear out my theory of the relation of atony to toxæmia He says[4] —

> *The whole of his intestines were much dilated and extremely thin, but no other lesion was found* [Italics are mine] Appendicostomy was performed in the hope of clearing the toxins from the colon The wound refused to heal at all though it remained antiseptic, and in spite of treatment the dilatation of the bowel persisted The bowels at last refused to act even when the colon was filled with water and although the small bowel was opened, he died apparently from complete inactivity of the intestines and extreme toxæmia some three weeks later

Acting on the belief that intestinal tone will check absorption I have found, when an attack on the intestinal content has partly or entirely failed (often without this preliminary), that treatment the observation that the early bullous manifestations of the disease were sterile.—Dr A. M H GRAY mentioned the recovery of a possible case of the disease and the PRESIDENT replied.

---

[3] R W Milligan THE LANCET Dec 31st 1881 p 1152.

[4] Proceedings of the Royal Society of Medicine 1913 vol vi p 1

Dr PERNET showed a case of Erythema Centrifugum which corresponded to the disease originally described by Hebra as seborrhœa congestiva.

Dr H W BARBER brought forward a case of Pityriasis Rubra Pilaris typical as regards its elementary lesions and distribution on the hands feet scalp and trunk, in a woman aged 41, in the seventh month of pregnancy She had previously given birth to seven children —The PRESIDENT thought that the association of the skin disease with pregnancy was fortuitous —The case was discussed by Dr WHITFIELD and Dr PERNET

Dr SEQUEIRA exhibited a case of Dry Gangrene of Several Toes of Obscure Etiology in an Infant.—Dr PERNET suggested the possibility of the existence of Raynaud s disease dependent upon congenital syphilis and this view was emphasised by Dr F PARKES WEBER and Dr A. DOUGLAS HEATH —Dr WHITFIELD and Dr BARBER also discussed the case —Dr SEQUEIRA replied that the case would be further investigated as regards congenital syphilis, of which he saw no evidence

Dr MACLEOD presented a woman with Eczematoid Ringworm of the Hand, presumably contracted from her children, who were suffering from small spore ringworm of the scalp He had reason for thinking that the infection was originally of feline origin and cited Dr Colcott Fox s observations on the subject.—The PRESIDENT and Dr SEQUEIRA referred to the frequent discovery of epidermophyton fungus in lesions of the hands which without microscopic examination would have passed as dysidrosis or vesicular eczema —Dr S E DORE referred to the frequency of cat ringworm in this country as compared with its rarity in France —Dr PERNET alluded to a case of feline microsporon ringworm which he had reported some years ago

Dr SEQUEIRA showed a Bristle from a Hair brush bearing numerous Ova of the Pig Louse (Hæmatopinus suis) which was however, not communicable to man

Dr ALFRED EDDOWES brought forward a case of Recurrent Circinate Erythema in a child

Mr T P BEDDOES showed a case of Extreme Hyperidrosis of the Hands of lifelong duration in a young woman —The PRESIDENT, Mr H C SAMUEL and Dr SEQUEIRA discussed the case

Dr E G GRAHAM LITTLE showed the following cases 1 A case of Typical Lichen Spinulosus in a child, which supported his contention that the disease had no relationship to lichen planus 2 A case of Parapsoriasis en Plaques 3 A case of Unusually Inflammatory Pityriasis Rosea.—Dr SEQUEIRA and Dr EDDOWES agreed as to the occurrence of an epidemic of pityriasis rosea at the present time and the PRESIDENT while agreeing with the exhibitor s diagnosis pointed out the difficulty of differentiating it from acute seborrhœa of the body

MEDICAL SOCIETY OF LONDON

Radiography in its Relation to the Present War

A MEETING of this society was held on Jan 25th, Sir J BLAND SUTTON the President being in the chair

Dr W IRONSIDE BRUCE demonstrated and read a paper on an X Ray Director for the Removal of Foreign Bodies in the Tissues which will appear in an early issue of THE LANCET —Sir J MACKENZIE DAVIDSON complimented Dr Ironside Bruce on his apparatus describing it as ingenious and remarkably accurate —Mr DONALD J ARMOUR said that he could bear out all that had been said with regard to its value.—Mr S MAYNARD SMITH said that he always used an X ray screen during the actual extraction of foreign bodies and had never experienced any difficulty from the point of view of sepsis being introduced He welcomed the improved method demonstrated by Dr Ironside Bruce

Sir JAMES MACKENZIE DAVIDSON gave an address on the Telephone Attachment in Surgery, and demonstrated the use of the telephonic probe His address is published in full on p 217 of our present issue —Mr ARMOUR described a case in which he had used this method for the removal of a piece of shrapnel which had lodged within the orbit. It was 3 mm. in width and lay 12 mm from the surface The operation which might have been a difficult one was thus rendered easy

Dr F HOWARD HUMPHRIS exhibited lantern slides of Injuries occurring among the Wounded at the 3rd London General Hospital Among the radiograms were some showing that bullets had penetrated through bone, producing little injury to it. Two other radiograms showed bullets lying against the pericardium The patient who had been wounded by one of these, had returned to the front with the bullet still *in situ*

The meeting was adjourned until Feb 22nd, when further contributions will be made by Dr A. C Jordan, Dr G Harrison Orton Mr S Gilbert Scott, Dr Stanley Melville, and Dr Robert Knox.

LIVERPOOL MEDICAL INSTITUTION

Pityriasis Rubra —Treatment of Displacement of Uterus —Incoördination of Function in Relation to Disease

A MEETING of this society was held on Dec 17th, 1914, Dr E W HOPE the President being in the chair

Dr F H. BARENDT read a note on Pityriasis Rubra and showed a patient. He referred to three cases, discussing one in detail.—The PRESIDENT and Dr R W MACKENNA discussed the note, and Dr BARENDT replied.

Dr A. STOOKES described a new electro-cautery for intra uterine work, and read a note on the Treatment of Displacement of the Uterus. He believed in the existence of discomfort in cases of uncomplicated retroversion, and he described several forms of operation

Dr C J MACALISTER submitted an interesting paper on Incoördination of Function in Relation to Disease He defined the subject and then described the interdependence of the organic functions showing that disease of one kind may produce symptoms referable to another In his opinion gastric ulcer was possibly associated with defective chemical coördination due to the climacteric of puberty, Raynaud s symptoms being prodromal in nature He instanced psychoses in children which in his opinion depended upon the chemical incoördination He gave several instances of marked improvement under thyroid —The PRESIDENT emphasised the value of education as a therapeutic agent —Major T R BRADSHAW Captain W B WARRINGTON and Dr A S PARKINSON discussed the paper, and Dr MACALISTER replied

At the annual meeting of this society, held on Jan 21st, the following list of office bearers and members of council was adopted —President E W Hope Vice-Presidents R J M Buchanan Alexander Stookes, R J Hamilton, and W J Fleetwood Treasurer Llewellyn Morgan General Secretary Frank H Barendt Secretary of Ordinary Meetings John Hay Secretary of Pathological Meetings D Moore Alexander Librarian Nathan Raw Editor of the Journal R. W Mackenna Council V C De Boinville James Huskie Robert Jones W McAfee A C Ransome, J H Willett, Claude Rundle Reginald T Bailey, Thomas Guthrie F M Gardner Medwin, W Allen Daley W C Oram and Gerald Wallace Auditors V C De Boinville and P F Tinne

---

METROPOLITAN HOSPITAL SUNDAY FUND—At a council meeting of this Fund held at the Mansion House on Jan 20th under the presidency of the Lord Mayor the various committees were re-elected, with the addition of the Rev Hardy Harwood to the distribution committee, the Rev H. A. Hall to the general purposes committee and Mr John Robarts to the finance committee Sir Ernest Tritton Bart was appointed vice-chairman of the Fund and the honorary secretaries and the auditors were re elected During the course of the proceedings sympathetic reference was made to the death of Mr Thomas Bryant who had been a member of the council for 22 years and on the motion of Sir Ernest Tritton it was unanimously agreed to send a letter of condolence to members of the family In replying to a vote of thanks the Lord Mayor said that he would do everything possible to assist the Fund, which was one of the most excellent movements in the country cheeks, and although somewhat wasted (weight 11 lb 6 oz) yet looked tolerably well There was no tenderness on handling and no swellings about the legs or arms There were no teeth, and the gums were in excellent condition A provisional diagnosis of infantile scurvy was made, and the child admitted as an in patient She was placed on equal parts of "raw" milk and water One teaspoonful of raw meat juice was given every three hours, alternatively with a similar quantity of orange juice The affected eyelid was treated with compresses of hydrogen peroxide The improvement in the state of the eyelid was striking Two days after admission the condition was less marked A couple of days later the baby could open the eye somewhat, and seven days after admission the eye could be widely opened, and the lower lid, although blood stained like a "black eye," was not swollen In fact, in the course of a single week under antiscorbutic diet changes had taken place that in ordinary cases would have been spread over three weeks or a month The infant's general health, unfortunately, did not improve *pari passu* with the local condition and the child died on Jan 18th from pneumonia and pneumococcal meningitis

Mr SYDNEY STEPHENSON and Dr SYDNEY A OWEN showed a case of Polio encephalitis Inferior of the Oculomotor Type in a girl aged 8 years She had gone to bed in her usual health, and the next morning "the eye was turned" and she complained of pain over her right brow Examination three days later showed slight ptosis of the right eye which was deviated outwards and upwards There was a defect in the downward and inward excursions of the eye The secondary deviation was outwards and a little downwards Diplopia was crossed, the false image being at a lower level than the true its upper end inclined outwards The signs therefore indicated a paresis of the inferior rectus of the right eye The right pupil measured 6 5 mm and the left 5 mm The latter responded actively to light but the former was sluggish There were no other signs of nervous disease

Dr SHEFFIELD NEAVE showed a case of Infantile Paralysis with Excessive Knee jerk in a boy aged 2 years The right leg showed flaccid paralysis deficient response to electrical stimuli, wasting of the calf muscles, excessive knee jerk and extensor plantar response

Dr J D ROLLESTON reported a case of Congenital Heart Disease and Ulcerative Sore Throat. A male infant aged 11 months, was admitted to hospital on Dec 6th, 1914, certified to be suffering from diphtheria, on the eleventh day of disease The father had always been healthy, but the mother had been an in patient at the Brompton Hospital on several occasions for rheumatism with cardiac complications The child had always been delicate and blue from birth Clubbing of the fingers had been noticed since he was aged 2 months On admission the child appeared to be very ill There were membrane on the tonsils, pillar, and uvula and a profuse nasal discharge The heart sounds were clear but rapid There was a trace of albumin in the urine. A large dose of antitoxin was given on admission and on the following day A few organisms resembling diphtheria bacilli were found in the cultures but cocci were predominant On Dec 8th a loud systolic murmur was audible all over the præcordium There was marked ulceration of both tonsils No Vincent's organisms were found in the throat smears The ulceration gradually spread over the uvula and palate On the 13th stridor and a hoarse cough developed, and there was much difficulty in swallowing The symptoms persisted and the general condition became worse until death took place from bronchopneumonia on the 20th The heart showed the following anomalies (1) Transposition of the great arterial stems the aorta arising from the infundibulum of the right ventricle and the pulmonary artery from the left ventricle, (2) marked deficiency of the interauricular septum which was represented by a narrow band 1 5 cm long by 0 5 cm broad (the foramen primum lay anterior to it and posteriorly there was a widely patent foramen ovale), (3) an interventricular foramen 1 2 cm in diameter in the 'undefended space', and (4) stenosis and hypoplasia of the pulmonary artery, the valve of which had only two cusps The fauces and larynx showed ulceration of the tonsils frenum epiglottis right aryteno-epiglottidean fold and deep ulceration of the laryngeal portion of the pharynx on each side especially on the left exposing the muscular tissue and eroding the thyroid cartilage

Dr J PORTER PARKINSON showed a specimen of Acute Atrophy of the Liver The patient a girl aged 5¼ years, had had jaundice for five weeks At first the liver was enlarged, and had gradually got smaller till it could no longer be felt The urine contained bile pigment and acetone, but no albumin, leucin, or tyrosin Delirium set in and death took place Post mortem the liver weighed 1¼ lb, was pale yellow and very friable On section it showed yellow areas between which were small dark red spots The gall bladder and ducts were normal Microscopically there was general staining with bile pigment The cells were distended with fat but the nuclei were well marked There was no distension of the bile ducts and no actual necrosis of the cells No micro-organisms were found in the specimens

Dr E B GUNSON showed specimens from a case of Suprarenal Hæmorrhage in an infant The child was first seen on the sixth day after birth There was a slight discharge from the umbilicus the cord having separated On the eighth day the temperature rose suddenly to 102° F and cellulitis of the forearm developed The stools became frequent, loose, and offensive The child was collapsed and died on the ninth day, 30 hours after the onset of symptoms Post mortem the right suprarenal was greatly enlarged and on section was found to have been converted into an almost black hæmorrhagic pulp The left suprarenal was similarly affected but to a less extent A culture from the heart's blood gave a pure growth of streptococcus A Gram stained preparation of the left suprarenal showed the presence both in the cortex and medulla of streptococci

Dr GUNSON also showed a photograph of a case of Purpura complicating diphtheria The purpura appeared at the site of an antitoxin rash and persisted till death Before death the purpuric patches on the cheeks and ears became confluent Superficial ulceration occurred, but there was very little loss of substance Hæmorrhages occurred into the gums and an extensive subconjunctival hæmorrhage appeared in the right eye There was old standing constipation, the stools resulting from the administration of castor oil and turpentine being very copious and markedly offensive for many days Palatal palsy carditis with "cardiac paralysis," arthritis, and albuminuria developed before death on the twenty eighth day

Dr F J POYNTON and Mr T T HIGGINS showed specimens illustrating a Persistent Pharyngeal Rudiment occurring in an infant aged 5 months Some difficulty in swallowing, associated with coughing and occasional dyspnœa, had been noticed for five weeks A pearly white rounded polypoid tumour was discovered in the pharynx and under anæsthesia was demonstrated to spring from the left supratonsillar fossa, being attached in this position by a narrow fibrous stalk After removal it proved to contain a narrow bar of cartilage embedded in fibrous connective tissue, exactly resembling subcutaneous tissue, and covered by perfectly formed skin

---

SECTION OF DERMATOLOGY

Exhibition of Cases

A MEETING of this section was held on Jan 21st Dr J J PRINGLE the President, being in the chair

The PRESIDENT showed a case of Pemphigus Vegetans in a soldier aged 28 The disease began in September 1914 and presented the characteristic bullous lesions on the skin and mucous membranes in abundance and vegetative condylomatous lesions in the armpits The serum obtained from the recent blebs was sterile but pus infection rapidly ensued and the case presented marked evidences of sepsis throughout its duration Remarkable improvement had taken place under treatment by vaccines of four varieties of coliform bacilli found in the fæces and of staphylococci and bacillus proteus from his bullæ, but probably much of his improvement was due to prolonged baths and other local antiseptic measures —Dr G PERNET commented on the unusually benign course of the disease contrasting it with others he had observed —*Dr A* WHITFIELD referred to a case of pemphigus vegetans in which the bullous element was very imperfectly developed —Dr J H SEQUEIRA related the history of a severe case of the disease which had apparently recovered despite his unfavourable prognosis, he discussed the relationship of the condition to dermatitis herpetiformis —Dr J M H MACLEOD confirmed that there is something profound and absolute in it, quite apart from the mere sequence of one moment upon another—is an empty simile, from which no genuine concept arises Indeed, it is not possible to understand Bergson's theory unless we visualise time as though it were space, and the theory falls to the ground the moment we abstract from his conception of time those spatial attributes without which that conception could never have been attained Mr Carr, taking a cross section through time, is clearly visualising, not time, but space, and what he and Bergson choose to call time is really a sort of hyperborean space conjured up by an alert imagination

Whether or not we agree with Mr Carr—and in philosophy that is largely a matter of temperament —we are bound to admit that his book is able, remarkably lucid, and conspicuous throughout for its sincerity and honesty of purpose If it is true of philosophy, as Gibbon suggested, that "her gentle hand alone is able to eradicate from the human mind the latent and deadly principle of fanaticism," then we may affirm that Mr Carr's book is wholly worthy of this exalted ideal Especially at the present time we cordially wish it the wide success which it deserves

The Book of Pharmacopœias and Unofficial Formularies

By E W LUCAS F I C, F C S, and H B STEVENS, F I C F C S London J and A. Churchill 1915 Pp 524 Price 7*s* 6*d* net

THE compilation of this book must have entailed considerable labour and much industrious research It is an attempt to present in a simple comparative form the formulas contained in the pharmacopœias of Great Britain, the United States, France, Germany, and Italy It also includes copious extracts from the unofficial formularies of these countries, as well as from the pharmacopœias of the leading London hospitals As a work of reference this book will certainly be of far more value to the dispensing and manufacturing chemist than to the medical man, by the former class many valuable suggestions may be gathered from a careful consideration of the reasons which determine the differences between the formulas of the various countries It is to be feared, however, that prescribers, especially at the present time, may maintain the attitude of Gallio, and pass by numerous small points which might improve their prescriptions

An initial difficulty was apparently experienced in the nomenclature, and the authors have wisely made the arrangement under the "commonly used Latin name, regardless of the question whether the name selected is that which is officially recognised in this country Under the title a series of synonyms is placed, and here again there is no indication of the countries if any, in which these synonyms are official The geographical range of employment has to be gathered from the reader's ideas of foreign languages, the synonyms may be those familiar in this country they may be alternative titles used to conceal the true composition, or they may be the official names from one or other of the foreign pharmacopœias to which reference is made The actual comparison of the composition and mode of preparation is facilitated by arrangement in parallel columns under the headings of abbreviated titles of the source, while the process employed is shown by affixing an arbitrary letter, which is explained in an appendix It is thus easy to see at a glance that extract of opium is of the same strength in the five pharmacopœias, that in all the same quantity of opium is used, but that in one instance the process of extraction differs from that adopted in the other four

In a book published subsequent to the new British Pharmacopœia, it is to be regretted that the metric system has not been adopted, the authors state that the imperial system of weights and measures has been adhered to, since it is the system still in general use by medical men and pharmacists It may be true that this procedure will save time and trouble involved in making the necessary calculations when a few ounces of any preparation are required, but the whole point of the introduction of the metric system seems to have been overlooked—viz, the facility of dealing with foreign prescriptions, which are invariably written in metric terms The avoidance of the metric system is the more surprising since temperatures are expressed in degrees Centigrade, instead of Fahrenheit Throughout the book, under sectional headings, there are numerous valuable directions about methods of preparation, these are most detailed in connexion with the extracts, which should be easy to prepare from the information afforded. For the tinctures the same amount of care has not been expended. Reference is made to the processes of solution, maceration, and percolation, but under the individual preparation we find no clue to the special process to be adopted, though the strength of alcohol is noted, and clear indication is given as to when the liquid should be weighed and when it should be measured A materia medica table, consisting of a dozen pages, gives the French, German, or Italian names of plants or parts of plants, together with their English equivalents These tables will save much trouble in enabling the pharmacist to identify strange names with familiar articles Although considered by the authors to be a table of vegetable materia medica it includes lard, honey, and leeches, but the foreign equivalents are so unlike the English terms that we ought not to cavil at finding them in such strange company

Viewed as a whole this book is likely to be of great service to pharmacists, especially to those who are called upon to dispense foreign prescriptions The probability of the early need of a new edition has led us to indicate directions in which it may be improved by the removal of minor blemishes or by the addition of further detail

Physiological Principles in Treatment

By W LANGDON BROWN M A., M D Cantab, F R C P Lond, Assistant Physician to St Bartholomew's Hospital, &c Third edition London Baillière, Tindall, and Cox. 1914 Pp 408 Price 5*s*

IN reviewing previous editions of this book[1] we called attention to the fact that advances in physiology often fail for many years to find themselves reflected in clinical work, and indicated that the task set himself by the author was to bridge the gulf between the experimental laboratory and the sick ward, and to reconcile physiology with therapeutics, offering to the general practitioner, to whom the work is addressed, a physiological reason for the therapeutic faith

---

[1] THE LANCET Dec 26th 1908, and Feb 18th, 1911

Reviews and Notices of Books.

Tuberculosis of the Bones and Joints in Children

By JOHN FRASER, M D, Ch M Edin., F R C S Edin, Assistant Surgeon, Royal Hospital for Sick Children, Edinburgh With 51 plates and 164 illustrations London Adam and Charles Black 1914 Pp 352 Price 15s net

Mr John Fraser's monograph is inscribed to Mr Harold Stiles If it is thus to a certain extent "placed," it will be generally admitted that it is well placed, and at the same time there is internal evidence that the author has spared no pains to form an individual opinion upon theory and practice Mr Fraser is canny His cautious "conclusions" on p 91 as to the value of tuberculins in treatment might strike the vaccinist as an exercise in the gentle art of damning with faint praise Throughout, too, there may be discerned a reserve in dogmatising which is natural enough when associated with such an extensive study of the literature as is implicit in the text, even if, in view of a modest disclaimer in the preface, it may not be deduced from the extensive and valuable bibliographies at the end of each section

The book is divided into two main sections "general," dealing with etiology and pathology, clinical features and diagnosis of bone and joint tuberculosis, X ray appearances, prognosis and the broad lines of treatment, and "special," dealing seriatim with regional lesions in their more particular aspects and detailed treatment The special section is thoroughly well done, with a wide and at the same time a distinctive outlook, but there is little in it that may not be found in other recent works on the subject It is the general section, and more particularly the extensive study of bone tuberculosis, its etiology, morbid anatomy, and histology, which will be read with attention by all interested Mr Fraser's arguments are rendered more cogent and lucid by the numerous and successful microphotographs and photographs With the general lines of vascular access and spread and close dependence on the distribution of vessels most readers will be familiar and in agreement, whether the latter factor has quite the degree of dominance here accorded will need further consideration in relation to similar phenomena of the more acute infections The footnote on p 26, in which Mr Fraser records a modification of his textual opinion as to the hypertrophic bone lesions of tuberculosis, is of great interest for several reasons it indicates his frank attitude of scientific doubt, it hints at the probably not infrequent association of the syphilitic with the tuberculous virus, whether simultaneous or sequential, and it may lead to an inquiry whether the hypertrophic lesion may not be, at least very often, the indication of association of another organism—for example, the staphylococcus—and not the product of the tubercle bacillus alone It was to be expected, but cannot be too often reiterated, that the bovine bacillus should be found responsible for a large proportion of the cases of infection in children —Mr Fraser found 60 per cent of a series of 70 examined bacteriologically, and that the milk supply is to be held ever suspect Hyperæmic treatment is praised somewhat lukewarmly, a distinction as to efficiency being drawn in favour of the upper as against the lower limb, and the positive statement is made that the formation of cold abscesses is hastened by it With regard to aspiration of abscesses and the injection of medicaments, whilst the various methods are indicated the reader is left to deduce that the author either does not practise them or has no high opinion of their utility, his attitude is somewhat similar towards the employment of injections for sinuses

The special section is uniformly good on conventional lines, here and there it is possible to pick holes—for example, in the paragraph "diagnosis," on p 299, of dactylitis, but the faults are venial and the merits considerable The whole monograph will repay reading and must prove of value both to students and surgeons of experience

---

The Philosophy of Change a Study of the Fundamental Principle of the Philosophy of Bergson

By H WILDON CARR London Macmillan and Co 1914 Pp 216 Price 6s 8d net

THIS book is founded upon a course of lectures delivered by the author in the University of London It deals, as the title indicates, with the philosophy of Bergson It is, however, much more than a mere commentary upon that philosophy The author's main preoccupation is with the relation of mind and body, matter and spirit, and it is this problem which he seeks to interpret in the light of what he calls the philosophy of change The view now prevalent among physiologists is that which regards all conduct and activity as depending exclusively on the material processes taking place in the brain and nervous system No active efficiency is attributed to mind, which is regarded as a mere phosphorescence, or "epiphenomenon," occurring in conjunction with certain cerebral processes, but having no power to affect their evolution in any way This view is attacked by Mr Carr Although he is unable to offer any valid arguments against the all sufficiency of cerebral processes in accounting for human activities —a theory which, indeed, is rapidly becoming an axiom of physiology—yet he does advance weighty reasons against the view that mind is a passive accompaniment of another order from the brain The argument, which is of metaphysical character and too long to reproduce here, does not, however, seem to us to have any force against what is called the double aspect theory—namely, that mental and cerebral processes are not two different things, but two different aspects of the same thing This, as Mr Carr is well aware, is much the most powerful position of the mechanists, and it would have been preferable if he had directed his analysis against that rather than against an older and less tenable hypothesis, already widely abandoned What he does is to refute the earlier and more easily refuted theory, and then to announce that the more developed theory "comes to grief on the same rock"—a statement which many will regard as wholly unjustified

As regards matter and spirit, Mr Carr takes, of course, the Bergsonian view as to the special connexion of mind with time and of matter with space "A simultaneous cross section through space would reveal all the matter existent in the universe but would not reveal mind On the other hand a cross section through time would reveal mind but would not reveal body" It has often before been urged that Bergson's apotheosis of time—his view is a decided gain to secure a good groundwork, and this is well provided for in this book, which is clearly written and well arranged

Artrocaces (Artritis Tuberculosas) Por el Doctor D RICARDO LOZANO MONZÓN, Zaragoza Tipografia de G Casañal Pp (circa) 600 Price 15 pesetas —Dr Monzón divides his work on tuberculous arthritis into two parts, general and special In Part I he opens with a brief introduction dealing with the history of the subject, in which four periods are recognised, an archaic period of confusion, a middle period of rudimentary differential diagnosis between tuberculous and other arthritic affections, a modern period commencing with the discovery of the tubercle bacillus by Koch and its demonstration in scrofulous joints, and the present period of "therapeutic controversy" The remaining chapters of this division deal with etiology, pathological anatomy, symptomatology, prognosis, and treatment, general and local To the chapters on treatment are appended statistical tables summarising the operative work of the author and of Dr Rollier, of Leysin, up to the end of 1913 Parts II III, and IV deal respectively with tuberculous arthritic affections of the upper and lower extremities and of the trunk, each articulation being treated of individually A brief account is given in Part V of tuberculous polyarthritis or tuberculous rheumatism of Poncet A useful bibliography completes this portion of the book, the remaining pages being devoted to illustrations of which there are no fewer than 196

Clean Water and How to Get It By ALLEN HAZEN Second edition, revised and enlarged London Chapman and Hall, Limited, New York John Wiley and Sons 1914 Pp 196 Price 6*s* 6*d* net —This book contains interesting statistics in connexion with questions of communal water supply General principles of course apply to every country The references here given are limited to the water undertakings in the United States but valuable lessons are given to all water engineers and public health authorities We spoke favourably of this book on the occasion of the first issue in 1907 It has now been brought up to date and into line with the progression made in water engineering schemes

JOURNALS AND MAGAZINES

British Journal of Tuberculosis —In the January number Dr Kenneth Fraser discusses in a commended M D Thesis of the University of Edinburgh early pulmonary tuberculosis in childhood On the basis of an examination of approximately 300 cases of pulmonary tuberculosis mostly incipient among 29 750 elementary school children in Cumberland an investigation was conducted into age incidence weight and nutrition the meaning of night sweats the occurrence of cough the pathological condition of the lungs the detection of pulmonary dulness the presence of accompaniments and the character of breath sounds In relation to children Dr Fraser suggests the expression inadequate increase of weight in place of failure to put on weight or loss of weight for physiologically even the phthisical child is automatically increasing in weight year by year Among his conclusions he considers inadequate increase of weight as very suspicious defective nutrition as probably the earliest indication of tuberculous infection, inequality of breath sounds as a very early indication of which friction and fine crepitations are the most significant accompaniments though all accompaniments are suspicious if persistent and especially if localised —Mr H Morriston Davies discusses the surgical aspects of pulmonary tuberculosis immobilisation of the lung and obliteration of cavities and the selection of cases suitable for treatment by immobilisation —Mr Harold Barwell reviews recent views on laryngeal tuberculosis, Mr Godfrey B Dixon considers the domiciliary treatment of tuberculous patients, and Dr William Cox discipline and recreation in the sanatorium —Dr Thomas D Lister in an illustrated article describes an apparatus for the production of artificial pneumothorax based on that of H de Carle Woodcock, of Leeds, oxygen being added to the nitrogen used in the former

Science Progress —The January issue, after an article on Militarism and Party Politics, contains a sympathetic criticism by Mr H G Plimmer, F R S, of Mr T A Cook s book, "The Curves of Life," which was reviewed in our columns recently —Miss L S Stebbing replies to Dr C A Mercier s article in the October issue on Some Logical Impossibilities suggesting that the syllogism is not the exclusive form of all argument and secondly, that Dr Mercier s non syllogistic arguments are merely syllogisms in disguise, depending for their validity on an unexpressed but necessarily implied proposition —Mr Hugh Elliot presents us with a survey of the problem of vitalism showing the ground already traversed by controversialists, examining the types of arguments used, and estimating the position now reached His trend is mechanistic —Mr Allan Ferguson discusses Capillary Constants and their Measurements and suggests that inasmuch as in a large number of papers dealing with this subject the multitude of units in which surface tensions are given causes a great deal of trouble much labour would be saved to those engaged in comparing the accuracy of different methods and searching for general results connecting capillarity and constitution if capillary constants were invariably expressed in C G S units—surface tensions in dynes per centimetre, and specific cohesions in square centimetres —Mr J N Pring, in a paper on the Formation of Ozone in the Upper Atmosphere and its Influence on the Optical Properties of the Sky considers certain factors which determine the optical properties of the atmosphere, and discusses the chemical estimation and distinction of some constituents of the atmosphere the action of ultra violet light on air the estimation of ozone in the atmosphere at high altitudes, and the influence of ozone on the nature of light from the sky —Dr F W Edridge Green discusses colour vision and colour vision theories including the theory of vision, and incidentally enters a very cogent protest against the official scientific methods of accepting or rejecting papers —A paper on the International Struggle for Manufactures as Illustrated by the History of the Alum Trade by Mr Rhys Jenkins, is followed by an illustrated article by Mr C Edward Wallis on Ancient and Modern Dentistry which contains considerable interesting material It should be mentioned that in the notes following the articles is one on the Society of Members of the Royal College of Surgeons of England with an exposition of its aims and a statement of the chain of events which called it into existence.

British Journal of Inebriety —The principal feature of the January number is an article by Dr R Armstrong-Jones on Drug Addiction in Relation to Mental Disorder The author considers the question in the light of his experience as an asylum physician, basing his remarks on observations of some 40 cases of drug takers in whom mental deterioration reached the degree of certifiable insanity With regard to such cases as with the similar cases of alcoholic intemperance, the question naturally arises whether the drug habit is to be considered as the cause or the consequence of the mental disorder Dr Armstrong-Jones s reply to this question is that while in most if not in all instances a certain degree of nervous abnormality must be admitted as an antecedent condition it is clearly evident on the other hand, that without the aggravating influence of the intoxication the graver destructive changes in the neurotic organisation would not have occurred at all or at all events would have been much later in developing And this fact is of practical account, for the reason that abnormal individuals of this class frequently possess by virtue of their very abnormality special endowments notably in the way of artistic and literary aptitudes which give a high social value to their work In agreement with the majority of observers Dr Armstrong-Jones finds that opium or some derivative of opium generally morphia is the most important of the habit-forming drugs Next in order of frequency come the new synthetic sedatives, amongst which veronal is especially that is or ought to be in him We also gave expression to a high opinion of its merits

The time that has elapsed since the second edition was published has necessitated very thorough review, and has led to some rearrangements and the addition of two chapters One of these chapters deals at length with the mechanical factors in indigestion Attention is drawn to "spasmodic hour glass contraction" Much controversy has centred round the question of the existence of a "middle sphincter" in the stomach It is known that under abnormal stimuli the circular muscle at the beginning of the pyloric vestibule is capable of powerfully contracting and dividing the gastric lumen The condition is liable to be mistaken for an organic hour glass contraction Dr Brown expresses the view that the spasm is usually due to the presence of an ulcer, which is generally situated on the lesser curvature, and may be quite small But it may occur in other conditions, and we think that he is probably right in the belief that the symptoms in so called 'appendix dyspepsia" are in part at any rate due to such reflex spasm A chapter which is partly new, is headed "Albuminuria and the Treatment of Nephritis" The difficulties in arranging the diet are duly discussed, and it is rightly pointed out that too rigid a limitation of the protein with the idea of diminishing the albuminuria is bad, because it cannot effect the desired object and deprives the patient of an essential form of nourishment On the other hand, an excessive protein diet is inadvisable, even if the patient can metabolise it, because he is getting the energy in a form that throws work on to the damaged excretory organs We agree with Dr Brown's contention that it is undesirable to restrict patients suffering from chronic nephritis to milk, which is too dilute a form of food for them, and may increase the œdema

There is much in this volume that is of value to the practitioner, the work is well written and affords interesting reading

---

The Operative Treatment of Fractures

By Sir W ARBUTHNOT LANE Bart, M S Lond, F R C S Eng, Senior Surgeon to Guy's Hospital and Emeritus Surgeon to the Hospital for Sick Children, Great Ormond street Second edition London The Medical Publishing Company, Limited 1914 Pp 184 Price 10s

Twenty two years have elapsed, the author tells us, since he made it his habitual practice to operate on all cases of simple fractures of the long bones in which he was not able to obtain accurate apposition of fragments, when the restoration of the bone to its normal form was of mechanical importance to the individual, and this statement expresses the idea of the book The reasons for all that the author does are clearly explained, and he describes the results that he has obtained

Opinions certainly differ on many points in relation to the systematic plating of bones, but all surgeons must acknowledge the ingenuity of the author's methods, the skilfulness of his manipulations, and the excellence of the results obtained Those who do not know at first hand the methods advocated by Sir Arbuthnot Lane will find in this volume what they wish to know, but they should see the author at work if they wish to appreciate fully what surgery can do in fractures

LIBRARY TABLE

Medical History Manuals Pasteur and After Pasteur By STEPHEN PAGET London Adam and Charles Black 1914 Pp 152 Price 3s 6d net—It is obvious that the history of medicine will soon have to be treated after the fashion of the Cambridge Histories—that is to say, in periods by specialists The book now before us is the first of a forthcoming series of Medical History Manuals to be published under the general editorship of Dr J D Comrie, future volumes of which are to deal with Greek and Roman Medicine, Mediæval Medicine, the Artist Anatomists of the Cinque Cento, Sydenham and Clinical Medicine, and the Predecessors of Lister, all by various writers expert in the subjects which they have undertaken In this volume Mr Paget has devoted the first 90 pages to a simply written resumé of Pasteur's life and work, derived in great measure, as he himself admits in his preface, from M Vallery Radot's "Vie de Pasteur" It is well that British readers who have not the time and possibly not the energy to embark on the study of the longer life should have the opportunity of studying the main facts of a life so unassuming, so earnest, so painstaking, and so fraught with benefit, both to man and the animal creation, as was Pasteur's Theology is called the queen of the sciences because it includes all the others, and for this reason, that the patient and humble study of Nature is a chief path that leads to a knowledge (as far as finite minds can understand the Infinite) of the Creator of all things And of Pasteur, whose studies into the secrets of Nature began with the humble "life" of crystals, it was said that "here was a man whose spiritual life was no less admirable than his scientific life" From Pasteur's labours came much of Lister's work and the understanding of, together with the ability to defeat, infective diseases, especially as Mr Paget shows, tuberculosis, diphtheria, cholera, plague, typhoid fever, Malta fever (known no longer by the unfair name), yellow fever, malaria It was from Pasteur's work on fermentation, putrefaction, the diseases of silkworms, anthrax, and many other phases of departure from health that other earnest workers found out how to fight disease, and no more simple or striking proof of this can be found than in the account of the stamping out of undulant fever as given in Mr Paget's excellent little book

The Elements of Chemistry By H Ll BASSETT, B A, B Sc With an introduction by Professor W J POPE, M A, F R S London Crosby Lockwood and Son 1914 Pp 368 Price 4s 6d—There is nothing strikingly original about this collection of principles and facts presenting, in the author's words, "as concisely as possible all the chemistry—general inorganic, organic, and practical—that is required for the Conjoint Board and First Medical Examinations' It will serve its purpose, however, if it is placed early enough in the hands of students who intend to pursue a medical or dental career, inasmuch if they digest so much chemistry before they join the hospital or university so much time will be saved The author has been careful to include just what is necessary While it is something more than an elementary school book, it avoids a stock of materials which for the time being, at any rate, are not essential Nowadays, of course the student of medicine finds that he must pursue chemistry considerably further than the mere elements, or his ideas of the great physiological processes will be most incomplete However, it

THE LANCET.

LONDON SATURDAY, JANUARY 30, 1915

The Dearer Loaf

THE rise in the price of wheat flour from 26s a sack before the war to the present figure of 45s is, of course, serious With the economic conditions which have led to this advance we do not propose to deal beyond expressing a belief that it is due not to a famine but to a shortage of labour and a resulting congestion of shipping If we are right the remedy is obvious, and its application should be simple and near and in that case there is no ground for panic, though some apprehension as to immediate effects is reasonable We look with confidence to the Cabinet Committee, recently appointed to consider the question of food supplies and prices, and presided over by the Prime Minister, to deal promptly with the conditions which are at the root of the present general advances All medical men and sanitarians are concerned in the question of applying scientific methods with a view of relieving the inconvenience of high prices when they prevail In a former article[1] we referred to the directions in which our food supplies could be augmented, and the present seems to be an opportune moment for returning to this subject We are inclined to think that the time has come to put aside a conventional contempt for or prejudice against so called substitutes, because it is undoubted that dietetically many of them can effectively replace certain articles of food for which only custom has reserved a place of respect in the common dietary So long as honest dealing is the rule, substitutes supply a common need in a way not appreciated in all quarters, their use, at any rate, would materially help the householder to keep his domestic expenses down while ministering equally to his physiological needs

For the present we may defer presenting the case for margarine or dripping as substitutes for butter, or glucose for dear sugar, and confine our attention to the loaf According to reports from Germany, attempts have already been made in that country to lighten the burden of the dear loaf by putting in it a notable proportion of potato or forms of potato flour Cheaper admixtures have been proposed, including materials possessing very little nourishing or even energy value at all We do not think that this country will be reduced to any such expedients But in the meantime it is just as well to consider how the loaf may be cheapened without affecting its energy value To the majority of people bread is not a source of nourishment, but only of energy To the extreme poor, often limited sadly enough to bread with butter or jam, the nitrogenous contents of the loaf become of very great importance It does not matter clearly to the man who can add to his bread some cheese or meat whether that bread is rich in nitrogenous material or not To the poor it matters a great deal, and that is a difficulty to be faced when suggestions are made to cheapen bread by mixing with wheat flour a cheap farinaceous substitute On this point some interesting observations are made by Dr E FRANKLAND ARMSTRONG in an article on the "Chemistry of Wheat and Flour"[2] He observes that flour is primarily a starchy material, but those characteristic properties which enable it to be made into bread are due almost entirely to the presence of some 10 per cent of nitrogenous material—the gluten Consequently from the point of view of the miller and baker gluten is the all important constituent of flour But to day, and somewhat irrationally, gluten has come to be regarded by the would be food expert as the essential constituent, overlooking the fact that bread is eaten primarily, not as a source of protein, but as an easily digestible, attractive form of starch The man in the street properly regards bread as equivalent to rice, potatoes, or the like, rather than as a substitute for meat, and it is not surprising, Dr ARMSTRONG thinks, that the academic reformers have failed to secure followers The proportion of gluten, we may point out, varies widely in different flours, and "grade" is based largely upon this fact It would be possible to add to rich gluten flours a proportion of starch, as, for example, cornflour, which is very much cheaper than wheat flour, without materially reducing the nitrogen value when compared with a low grade wheat flour The energy value of such a loaf would be quite high, while its nourishing properties would be little impaired If it should be feasible to introduce, say, 20 per cent of cornflour in this way into a strongly glutinous flour a very definite economy would be gained, and a loaf decidedly cheaper than the all wheat-flour loaf would be available for food purposes There are the probabilities, also, of increasing the "strength' of the gluten as a formative agent by activators such as phosphoric acid or phosphates which are not foreign ingredients of flour, thus it might be possible to increase the addition of cheap starchy materials still further Since the supply of pure maize starch is practically inexhaustible, and there has been no appreciable rise in its price—certainly no advance anything like that in wheat flour—the attention of our authorities may usefully be drawn to this suggestion It may be remembered that cornflour is amongst the most easily digested farinaceous foods prominent In several instances the drug habit appears to have been initiated by the use of quack remedies, such as various patent "headache powders " and "nerve tonics " Most of the patients were brain workers, and more than one third of them were doctors or nurses The average age on admission under asylum care was 40 years for males and 43 for females With regard to the mental symptoms which the patients presented, the most interesting points to note are the prominence of disorders of conduct and moral sense and the frequency of suicidal tendencies, which were observed in 57 per cent of the cases The paper concludes with an emphatic appeal for a more effective control of the sale of dangerous drugs —Dr Mary Scharlieb, Sir George Savage, and several other physicians contribute brief comments on the points discussed by Dr Armstrong Jones, and express their complete concurrence with his plea in favour of legislative action to check the evil of habitual drug-taking —A short article by Mr John Newton notes with approval the action of Russia in prohibiting the sale of vodka during the war, and quotes journalistic evidence as to the good effects that have followed this measure

[2] Nature Jan. 7th 1915.

Knowledge —A note in the January issue on obtaining chlorophyll and phycoërythrin from red seaweeds appears under the name of Mr W B Grove, and among the correspondence is a letter asking whether it is not possible to find a process by which the wool for woollen fabrics may be made not only aseptic but antiseptic The query is suggested by the statement that in the present war whenever serge from the clothing is carried into wounds by shell fragments the wound is more septic than is usually the case when it is similarly contaminated by shreds of linen

PLAGUE INVESTIGATIONS IN INDIA[1]

NINTH REPORT

THE Advisory Committee appointed by the Secretary of State for India the Royal Society, and the Lister Institute have recently issued their ninth report on plague investigations in India In continuation of previous inquiries directed to find out the reasons why some parts of India have suffered less from plague than others, the circumstances of the Madras Presidency were specially investigated In a previous report the comparative immunity of the city of Madras from plague was considered, and in the present inquiry the conditions of some other parts of the Presidency were examined by Major J O Kunhardt, I M S, and Captain J Taylor I M S, who were assisted in the work by five assistant surgeons of the Indian Medical Service.

Epidemiological Observations in the Madras Presidency

The portions of the Presidency specially inquired into were (1) the Bellary district, the Mysore plateau, and the Nilgiri Hills, which had suffered severely from plague, (2) a zone, which had suffered but slightly from plague lying immediately below and around the above mentioned areas, and (3) the east coast and southern part of the Presidency which had escaped the ravages of the disease A full description of these areas is given, including their physical features, climatic conditions distribution of plague, rat and flea prevalence, susceptibility of the local rats to the infection, and other matters 90 per cent of the plague deaths in the Madras Presidency were found to have occurred in certain districts which immediately adjoin infected areas in the Bombay Presidency and the State of Mysore In some years when the temperature has been lower and the humidity higher than normal plague has extended to places immediately adjacent to the infected areas of the Madras Presidency mentioned above and serious epidemics have developed in certain municipal towns while the disease in the surrounding villages had generally been mild Although the disease has invaded the Presidency it has shown little tendency to spread beyond the limits already indicated While the districts which suffered the most have the characteristic in common that they are in closest proximity to infected areas outside the Presidency they also resemble each other in being the most elevated and coolest parts of the province A low lying comparatively hot and dry plain separates the areas at present infected from the more humid and cooler coastal regions Plague has rarely occurred on the east coast, but on the west coast the seaport towns of Mangalore and Calicut which have intimate trade relations with Bombay, have suffered from the disease It appears then that the proximity to infected areas and the facilities for communication with them have been of more importance in determining plague incidence than climate in the Bellary district Kurnool, with a similar climate but more distant from infected centres and having also less rapid and efficient means of communication has suffered but little On the other hand, plague has been severe in the Nilgiris where the population is scattered and the means of communication are indifferent, but where the climate is very favourable for the spread of the disease The number of fleas found on rats depends to a great extent on the climate Experiments showed that rats caught in places in Madras which have been free from plague epidemics are very susceptible to the infection, and this is a favourable factor for the development of plague The existence of such susceptible rats at present in certain places in India, now that plague has continued there for a series of years, indicates that conditions exist in such places hindering the successful implanting of infection in them. It is difficult to determine what these conditions are, but the investigators are inclined to attribute this comparative immunity to the warm climate obtaining over the greater part of the Presidency As plague is carried from place to place in the bodies of infected fleas any local conditions affecting survival of these insects, apart from a host, are of importance in determining the liability of the neighbourhood to plague When separated from their host rat fleas speedily succumb to the combined effects of a high temperature and drying Unfavourable conditions of this kind are found in the hot and dry plains separating the cooler and moister sea coast districts from the existing plague infected areas in the Presidency This region breaks the chain of communication between the infected area on the west and the cooler regions of the east coast As no satisfactory harbour exists on the east coast of the Presidency where ships can discharge cargoes there are few facilities for the landing of infected rats The physical features and climate of the Madras Presidency, therefore, have an important influence in limiting the distribution of plague in it

Experimental Researches

Dr Sydney Rowland, of the Lister Institute, carried out a number of valuable researches, details of which are given in the report relating to plague including further experiments on vaccination against a body strain of plague, immunisation by *pseudo tubercle*, *immunisation* by living avirulent cultures, the influence of race on the efficiency of antigen, the failure to vaccinate against a virulent body strain even with an antigen prepared as far as possible under body conditions, the protection and curative value against infection with a serum race of plague of the serum of a horse immunised with nucleo-protein extracted from a strain of plague bacilli propagated on serum protein, and lastly ultra violet light as a germicide in the preparation of plague vaccine

Entomological Investigations

Mr A W Bacot, entomologist to the Lister Institute, made a series of observations on the length of time that fleas (Ceratophyllus fasciatus) carrying bacillus pestis in their alimentary canals are able to survive in the absence of a host and retain the power to re-infect with plague He also contributes to the report some further notes on the mechanism of the transmission of plague by fleas He supplies, likewise some notes with two illustrative plates on the development of bacillus pestis in bugs (*Cimex lectularius*) and their power to convey infection *He found* that the development of B pestis within the crop *of bugs* differs generally from *that* which takes place in *the stomach* of the flea in respect of its slower and looser growth this limitation of activity being accompanied by *and possibly* due to the preservation of the structural character *of the* blood for many days after its ingestion into the crop The absence of any definite valve between the pump and the crop, together with the looser nature of the growth within the bug preclude the idea of such mechanical blockage as causes regurgitation and mouth infection by fleas.

---

[1] The Journal of Hygiene Plague Supplement IV Being the Ninth Report on Plague Investigations in India Issued by the Advisory Committee The Cambridge University Press January 1915 Pp 109 With [illegible] maps and charts and [illegible] plates Price 7s net

in the present war, and he lays great stress on the need of using antitetanic serum early in cases of lacerated wounds The importance of ambulance ships is acknowledged, and therefore we are glad to see two papers on this subject. One is by Mr SEYMOUR BARLING, who points out that in the cases carried in ambulance ships there is an undue proportion of wounds of the upper and lower limbs, because the more serious wounds of the head, thorax, and abdomen remain in the hospitals of France Mr CHARLES A. PANNETT, serving in the hospital ship *Liberty* discusses in a practical way the fitting up of hospital ships, their personnel, and the transport of wounded Some very striking skiagrams taken by Captain HERSHEL HARRIS, of Sydney, accompany an account of radiography at the Australian Voluntary Hospital, Boulogne Mr WILLIAM THORBURN has described the work of the 2nd Western General Hospital and Mr GILBERT BARLING that of the 1st Southern General Hospital Mr D'ARCY POWER has contributed a note of a case in which gold coins were carried into the back by a shell fragment, and Mr W BALY PEACOCK has illustrated a case in which a pile of five franc pieces were deeply scored and bent by a bullet Lastly, we may mention an account of a visit to some of the military hospitals of Paris and Boulogne, an especially full account being given of the Hotel Majestic in Paris

It will be seen from these admirable professional journals that the medical profession, both naval, military, and civil, are doing their best for those who have suffered wounds and injuries in this war The energy with which the writers have managed to find time to put on paper some of the lessons which the war has already taught us is to be highly commended, while it is rapidly becoming clear that the whole subject of military surgery will require overhauling in our text books

---

SCOTTISH POOR LAW MEDICAL OFFICERS' ASSOCIATION —The council in its report for the year 1914 states that the number of vacant appointments was not so large as usual and the correspondence in connexion therewith was therefore considerably less The new Order issued by the Local Government Board came into force rendering all forms of tuberculosis notifiable A fee of 1*s* is payable by the local sanitary authorities in respect of each case occurring in parish practice, and 2*s* 6*d* for cases occurring in private practice The Highlands and Islands (Medical Service) Grant Act came into force and, from all the council has been able to learn will do much to render the position of medical officers in the Highlands and Islands much more satisfactory both in regard to remuneration and status It is especially noted that medical officers in the crofting counties now have an appeal to the Local Government Board in cases of dispute with their parish councils From all the information the council has gathered the National Insurance Act appears to be working to the benefit of both the medical officers and the public in sparsely populated districts The annual meeting of the association will be held in the North British Station Hotel Glasgow, to-day Friday Jan 29th, at 3 30 [illegible]

Annotations.

"Ne quid nimis"

THE BELGIAN STUDENT AND THE UNIVERSITY OF CAMBRIDGE

THE Master of Christ's College, Cambridge, Professor Shipley, writes —"We are gradually building up a little Belgian University here for students who, for one reason or another, cannot go to the front and for professors who are past the age of serving Altogether we have between 100 and 200 students and some 15 to 20 professors Last term we were able to establish effective teaching in four faculties and this term we have increased the number to six In the Faculty of Medicine we are in need of copies of some standard text book on human anatomy, preferably Gray's" The University of Cambridge has already found several thousand pounds to support her guests, and will have to find several thousands more to fulfil the obligations which she has undertaken, even if such a term is put to them as next June It will be necessary to husband resources very carefully, and it is not possible to purchase expensive text books It may be that some of our readers have copies of "Gray's Anatomy" lying unused on their shelves If this is so, the Master of Christ's College would be grateful if they would send them to him at Christ's College Lodge At present ten or a dozen copies would suffice, we are told

INSANITY IN EGYPT[1]

AGAIN we have to review a piece of most excellent work carried on in very trying conditions The report may be said to be a year old, but delay in publication was due to the stress of work which has fallen on Dr J Warnock in consequence of the tragic death of his able assistant during the year 1914 and the present apparent difficulty in replacing him The report is one of the most complete records of the work done and of the various lines of development which can be imagined It is a puzzle to understand how Dr Warnock can manage the big asylum and yet find time to enter into minute details His report is a mine of information which ought to be a field for all workers on developing institutions for the treatment of insanity We can only shortly refer to a few special points 1329 cases were treated during the year 1913 Pellagra showed an increase and is said to be the most frequent cause of insanity in Egypt As in former years, there was excess of admissions over the space for their reception, this excess being most on the men's side It is sad to notice that for want of accommodation over 200 cases were discharged while still insane, thus leading to returns of insane on the one hand and to criminal acts on the other The further development of Khanka under Dr H W Dudgeon did a good deal to relieve the acute pressure, and as a result of less crowding the recovery rate was increased In every part of the report there is evidence of strenuous and earnest work It is satisfactory to know that the Lunacy Department in Egypt is no longer part of the Public Health Department, but is under the

---

[1] Reports of Government Hospitals for the Insane at Abbasia and Khanka, Egypt for 1913

The movement for "standard" bread has been revived, for it is contended that the loaf production of the country would be increased from 10 to 20 per cent by using practically the whole of the grain By the rejection of the germ and by roller methods of refining flour it is urged that much valuable food material is lost That may be so, but it is doubtful whether the adoption of a standard bread will cheapen the loaf, for the separated germ is an independent source of revenue, and it is not a famine we are confronted with, but dearness arising out of reduced transport facilities To meet the difficulty we ought to use all ingenuity For example, the industrial use of low grade flours for "sizing" and "filling" purposes in the textile trades may want supervision from the food supply aspect Although described as low grade, there can be little doubt that such flours would serve for human food, and they can be replaced for this industrial purpose by "sizes" showing a lower food value We hope that the attention of the Cabinet Committee appointed to consider the question of food supplies and prices will be directed to the fact that very many thousand tons of wheat flour are annually used for "sizing" purposes in the textile industries And yet it is well known in the trade that the "sizing" process is by no means dependent upon wheat flour, and that other materials such as the plain starches can be used equally well for the purpose The Cabinet Committee will have evidence placed before it in many directions of the most interesting and important kind The result of its labours will be looked for anxiously, and success will follow if the reasons for any measures adopted are scientifically sound, and are explained in simple language to the public

Medicine and Surgery in War.

IT is only natural that at the present time, when all our energies are being devoted to the carrying on of a great war, that the *British Journal of Surgery* should contain little that is not connected in one way or another with war This month has also appeared the first number of a new medical quarterly, the *Journal of the Royal Naval Medical Service* This is edited by Fleet Surgeon R C MUNDAY and Fleet Surgeon W L MARTIN, and if from the first number we may gauge the value of the contents of succeeding issues it will form a most important addition to British medical literature Almost the only article in this number which is not directly concerned with war is that by Staff Surgeon E L ATKINSON, dealing with the British Antarctic Expedition from 1910 to 1913 Even this throws light on matters now affecting both our army and navy, for it treats *inter alia* of frost bites, various forms of which have been seen so widely of late in our army in Flanders. It is of interest to note that the snow of the Antarctic regions is too cold to be employed for rubbing a frozen nose or ear, though this may be the best treatment for frost bite in more temperate climes One of the most interesting papers is that by Fleet Surgeon WALTER K HOPKINS on the action off Heligoland, in which the value of an early and thorough cleansing of wounds is clearly shown, he was on duty 37 hours during and after the action, and evidently did an immense amount of work The difficulty of localising bullets in the body and limbs is sometimes very great, and the method suggested and described by Surgeon S BRADBURY is simple and appears to be very useful, it consists essentially in finding the position of the bullet from two aspects and then tracing its real position by means of a strip of lead This needs rotation of the limb through only a few degrees, and therefore little disturbance of the patient The paper on the prevention of typhoid fever by Fleet Surgeon P W BASSETT SMITH is timely, when we find preventive treatment of typhoid fever so violently assailed Of great interest and importance is the note by Surgeon SHELDON F DUDLEY on a typhoid carrier, the man was "ship's cooper" and therefore he was brought in contact with articles of food when opening casks, in 13 years he had served in 12 ships, and he had given rise to 53 cases of typhoid fever, of whom 11 had died Surgeon A VAVASOUR ELDER has written a valuable paper on ambulance trains, containing an account of Naval Train No I In this the cots are movable and not fixed, thus there is much less disturbance of the patient in taking him into and out of the train, and he is much less affected by the jarring of the train. We have said enough to show that in the *Journal of the Royal Naval Medical Service* we have a valuable addition to medicine

In the January number of the *British Journal of Surgery* are many important papers bearing on the war Lieutenant Colonel C B LAWSON and Mr. H BECKWITH WHITEHOUSE have published a communication on the treatment of acute emphysematous gangrene, a disease which has appeared with great frequency in the present war The treatment employed consists in the injection by means of a Higginson syringe of hydrogen peroxide into the healthy tissues three or four fingers breadth above the line of advancing gangrene, as shown by the dusky copper coloured tint of the skin It is essential that a complete belt of oxygen should be formed above the gangrene, and therefore several openings may be needed, and the dissemination of the oxygen must be aided by kneading and massage A certain amount of shock is produced, especially if the upper limb is affected, and general anæsthesia, or sometimes spinal anæsthesia, must be employed As to the results of 11 cases treated by infiltration 8 recovered while of the 3 cases not treated by infiltration all died Especially it seems to follow from these cases that amputation above the grangrene is not only not called for, but that it may be dangerous, for it may prove fatal from shock. Professor TUFFIER, of Paris, has written a short note on military surgery as seen anginal attacks, pulmonary signs, or enlargement of the liver There was no history of cardiac failure even in the slightest form Some of them returned to the front They all showed well marked aortic insufficiency with manifest hypertrophy of the left ventricle and peripheral signs In all cases the disease was of rheumatic origin In the discussion which followed M A Siredey and M de Massary reported cases in which on examination for life insurance they found to their surprise aortic insufficiency in strong and vigorous men given to sports and athletic exercises

FEBRILE CONDITIONS FOLLOWING OVARIECTOMY

IT has been frequently noticed that women who have been subjected to operative treatment for ablation of the ovaries present a rise of temperature of moderate intensity occurring without rigors and having a characteristic duration of 15 days, after which a condition of complete and absolute apyrexia becomes established During this febrile period the patients do not experience any general disturbance of importance, having recovered from the operative shock their general condition is satisfactory and cicatrisation of the wound takes place normally and without complications After 15 days the fever disappears and convalescence is established This thermic rise is met with in cases of simple ovariectomy for inflammatory conditions and also in those in which hysterectomy has been performed together with removal of the tubes and ovaries, but is especially frequent in cases of ovarian sclerosis with marked general nervous phenomena. Dr P Azara, in a recent issue of *Il Policlinico*, draws attention to this condition, in which the thermometer does not rise above 38° or 38 1° C, and offers an explanation of it Chiarugi had already described in his work on the surgery of the thyroid a "thyroid fever following excision of that organ and considered it due to the pouring into the circulation of thyroid secretion not yet elaborated, or altered by the pathological condition, or else modified by contact with the air Whatever clinical analogy exists between thyroid fever and ovarian fever Dr Azara is of opinion that Chiarugi's explanation is not applicable to the latter In the first place, the operative field in ovariectomy is altogether different as regards vascularity to the cervical, and, moreover, it is impossible to admit however remotely, the pouring into the circulation of "ovarin, which by accumulating in excess in the organism would produce a febrile condition Another theory, however, may be adduced to explain the ovarian fever Starting with the conception that the ovaries have an internal secretion, and admitting that the so called ovarin, a product of the corpus luteum, has a disintoxicant action on the organism, it follows that this action would be annulled by ablation of the ovaries and that the febrile condition would come to an end as soon as the organism had re established a certain equilibrium by means of the compensative action of some other organ with internal secretion

THE JARISH HERXHEIMER REACTION

THE Herxheimer reaction consists in a focal local and general reaction supervening in syphilitics at the outset of treatment with antispecific agents This reaction, when first described applied more fittingly to mercury It consisted in an aggravation of all the signs of the infection during the first days of treatment after two to five injections or inunctions Herxheimer believed that the reaction existed solely during the second stage of syphilis, but since it has been more fully studied in relation to its occurrence following salvarsan it has been found that this reaction appears equally readily at all stages The reaction, too, may be as varied as the forms of syphilis, cutaneous, visceral, or cerebral Thus the chancre may enlarge rapidly In the secondary stage there may be arthritis, headache, or even fever and meningitis, it is said that in the secondary stage 63 per cent have a syphilitic meningitis, shown by leucocytosis of the cerebro spinal fluid Amongst tabetics the reaction takes the form of transitory aphasia, acute delirium, or shooting pains, or it may be barely noticeable It was suggested that some part of the aggravation of symptoms might be due to the development of toxins derived from organisms in the diluting fluid used for the intravenous method, but this does not explain all the facts, as Dr K. M Benoit Simon points out in the *Canadian Practitioner and Review* (1914, vol xxxix, p 655) The reaction, in view of the gradual accumulation of fatal results after salvarsan (200 up to 1912), may deserve attention Dr Simon says that the reaction is proportionate to the intensity of the lesions, it is thus more marked in the secondary stage It is also proportionate to the dose of the antisyphilitic drug and its specific activity Two questions regarding the reaction may be asked is it useful or is it noxious, and if the latter, is it preventable? 1 The reaction is useless—all agree on this, it is also injurious the danger lying especially in the meningeal response 2 The reaction is preventable It is necessary first to seek dangerous localisations of the disease, especially a latent meningitis, lumbar puncture must be performed for the diagnosis of such a latent and potential source of trouble. Secondly, since a first dose must be blindly given, let it be the minimum which has never given accidents—that is, 0 2 gramme salvarsan for an adult—and watch The temperature and the cerebro spinal fluid being observed the dose can be increased gradually

INTRA-ARTICULAR FIXATION OF FRACTURES

WHILE the value of the fixation of fractures by apparatus inserted in the bone is established it is generally taught that no foreign substance should be inserted into joints However, it has recently been shown that intra articular fixation is possible In the *Maryland Medical Journal* for December, 1914, Professor Nathan Winslow has reported two cases in which he performed this operation A man aged 50 years had a fracture through the head and anatomical neck of the humerus in a bad position which could not be rectified by manipulation An incision was made midway between the acromion and the coracoid processes extending 7 inches down the arm The distal fragment was delivered through the incision Then the head of the bone was separated from its capsule and entirely delivered from the body The fragments were brought into apposition but the upper was so shattered that it offered but little surface for plating After some difficulty a very small plate was insecurely attached to the fragments It was necessary to pass a wire nail through the articular surface into the shaft of the bone The capsule was sutured the wound closed, and directorate of Dr Warnock, and is attached to the Ministry of the Interior There is a great gain in the addition of skilled English female nurses, as till these were sent women of the lowest class had to be employed Dr Warnock and Dr Dudgeon deserve the highest praise for their work and their report proves this

---

EXTRAORDINARY ACCIDENTS

IN our last issue we printed an account by Lieutenant T O Thompson, R A M C, of a patient who impaled himself on the handle of a hayfork The only noticeable lesion was a tear of the scrotum some three inches in length, but the fork handle had passed almost subcutaneously from the scrotum to the inter clavicular region, it had carried in with it some hay and also a portion of the patient's clothing The second rib was broken and much sepsis followed In spite of this severe injury the patient was able to walk three miles home and to drive thence ten miles to the hospital This case shows well that extensive internal injuries may be present as the result of an accident, and yet the obvious lesions may be small There is to be noted a curious sameness about lesions resulting from falling upon the handles of hay forks We may quote one from the *American Journal of the Medical Sciences* for 1853, there was reported a case which was under the care of Dr Sargent, of Worcester The patient was a lady 37 years of age, and she slipped down from a hay loft and impaled herself on the handle of a hayfork, the handle entered the vagina and penetrated 22 inches, and its entrance was stopped only by her feet touching the ground The handle was immediately withdrawn, and though the patient complained of some pain on the left side of the thorax she was wonderfully little affected Surgical emphysema developed above the left clavicle, and later it was found that the first rib on the left side was broken Several other similar cases have been recorded in which impalement has occurred with very little external evidence of injury In THE LANCET of 1885 we published an interesting case reported by Dr Shirtliff A coal porter was found dead on a railway line, showing only bruising of the abdomen and surgical emphysema of both sides of the abdomen and of the right side of the chest, yet at the necropsy the left pleural cavity was found to contain in addition to a large quantity of blood, the torn spleen, the stomach which had been separated both at its cardiac and its pyloric ends, and also a piece of the liver, these had passed through a large hole in the diaphragm In the right pleural cavity were also much blood and many small pieces of the liver, which had come through a small opening on the right side of the diaphragm Of the portion of liver which remained in the abdominal cavity much had been reduced to pulp, many of the branches of the mesenteric veins had been torn, and four yards of the intestine had been forced into the scrotum The bladder was ruptured and the aorta was torn through at the level of the tenth dorsal vertebra, which was fractured, many ribs were also fractured In this case the amount of external injury was utterly out of proportion with the damage which had been done to internal organs Every surgeon knows how slight may be the external evidence of injury when a cart wheel has passed over the abdomen, and yet a rupture of the intestine may have been caused Only a week or two ago the daily press reported that a child had been brought to a hospital after having received a blow in the abdomen. As the external injury was slight, and there were no signs that any internal viscus had been damaged, the child was sent home, but later the appearance of peritonitis showed that internal damage had been done, and it was found that rupture of the bladder had occurred It is difficult to lay down hard and fast rules, but it may be said that in all cases when the nature of the accident renders it possible that a severe injury to some internal viscus has occurred, even though no signs of it are present or can be elicited, it is wise to keep the patient under observation, so that at the first sign of internal injury manifesting itself surgical intervention may be available

SUBJECTS OF AORTIC INSUFFICIENCY IN THE FIGHTING LINE

IT has often been said with truth that our press has not done justice to the achievements of the French in the war The fault has not been due to any desire to overrate our exploits by underrating theirs, but partly to the secrecy which has largely veiled the military operations and partly to a naturally engrossing interest in the work of our own troops The want of appreciation is not so much of the valour of our Allies, for which no praise could be too great, but of the extraordinary efforts which they are making to confront a numerically greater military power The magnitude of these efforts is no doubt obscured by the fact that the French preparations for such a gigantic struggle were insufficient However, it must be remembered that complete preparedness could be expected only in the Power which planned the war and struck at what she conceived the opportune moment The extraordinary efforts now being made by France are strikingly shown by the willing and successful part taken in the campaign by the subjects of grave organic disease We recently called attention to the case of a tuberculous man, the subject of artificial pneumothorax, who successfully went through the arduous campaign in Northern France during the month of August and broke down only during a forced march[1] He was shown at the Societe Medicale des Hopitaux of Paris by M Rist At a subsequent meeting M Ch Aubertin reported cases in which the subjects of aortic insufficiency took part in the campaign Curiously, this flagrant violation of therapeutic rules was unattended by accidents While engaged during October at the Gare de l' Est in examining the sick and wounded arriving from the front he was surprised to find among them cases of aortic insufficiency During a fortnight he observed five among a relatively limited number of soldiers The ages of the patients ranged from 20 to 30 years One joined the army on his own demand, in spite of the lesion being found at the medical examination, the others did not know of the existence of the disease They all had taken full part in the campaign, including the battle of the Marne Some of them had marched as much as 30 kilometres a day with their knapsacks The trouble which caused them to be sent back as "*éclopés*" was almost always general fatigue rarely palpitation In no case could M Aubertin find œdema, arrhythmia dyspnœa

INTRAVENOUS TREATMENT OF ARTHRITIC PROCESSES

THERE are certain positive advantages obvious to the intravenous methods of giving drugs One is precision and accuracy of dosage with the certainty that the agent used will exert its effect unchanged by the disturbing factors which are necessarily associated with the ordinary absorptive processes from the gastro intestinal tract The other is rapidity of action Advantages accruing from precision of dosage are especially seen in the salvarsan treatment, the necessity for such accuracy being obvious The advantage of quickness of effect is most conspicuously noted, perhaps, in the intravenous injection of strophanthus in urgent cases of heart failure due to auricular fibrillation It is natural that intravenous medication should have been tried in other conditions, and some success is claimed for this method of giving salicylates for refractory cases of acute rheumatism Dr Albert Comstock records the details of this form of treatment in certain articular diseases in the *New York Medical Journal* (vol c, 1914, p 1113) He uses the following prescription —

R Guaiacolis—sodii salicylatis, ana gr	640
Glycerin	gr 640
Aq destill et steril	2000 c c

The conditions for which its intravenous use is indicated are acute articular rheumatism, acute and chronic muscular rheumatism, and acute gouty arthritis The patient is suitably prepared and an aperient given The quantity of the solution, at 100° to 110 F, used is 250 c c (*sic*) The vein is usually dissected out and the fluid slowly allowed to flow in The first subjective sign noted is a tingling sensation, with a coal tar taste in the mouth, due to the guaiacol The face then becomes suffused and congested and perspiration is free There is generally slight delirium, which may last for half an hour The pain, however, is relieved in a wonderful manner, and within 24 hours the patient is better This relief is most marked and most permanent in acute rheumatism, in 50 cases there has been no bad result In muscular rheumatism the result is not so good, and in the chronic form two or three injections may have to be made at intervals of three or four days For cases where salicylates given in the ordinary way cannot be tolerated by the stomach or in particularly obstinate cases this intravenous method is recommended

---

AT a meeting of the Council of the Royal College of Surgeons in Ireland held on Jan 21st, Mr F Conway Dwyer, President, in the chair Sir Arthur Chance was elected to represent the College at the meetings of the General Medical Council

---

Dr George Lovell Gulland, physician to the Edinburgh Royal Infirmary has been appointed to the Chair of Medicine in the University of Edinburgh, vacant through the resignation of Professor John Wyllie

---

AT a meeting of the Senate of the University of London held on Jan 27th Dr Edward Barclay Smith M A M D L C Camb was appointed to the University Chair of Anatomy at King's College London and Dr Edward Provan Cathcart, M D Ch B, D Sc Glasg, was appointed to the University Chair of Physiology (as from April 1st next), tenable at the London Hospital Medical College

THE CHADWICK LECTURES ON WAR AND DISEASE[1]

THE second of three Chadwick lectures was delivered at the Royal Society of Arts on Jan 22nd by Colonel F M SANDWITH, M D The chair was occupied by Sir FREDERICK TREVES, and there was a large attendance

Presentation of Chadwick Prizes and Medals

An interesting function preceded the delivery of the lecture—namely, the presentation to Fleet-Surgeon Cleveland Munday and Colonel Heaton Horrocks, R A M C, of the Chadwick Medal and £50 for distinguished services in promoting the health of the men in the navy and army respectively

Sir ARTHUR MAY, in thanking the Chadwick trustees for the honour they had conferred on the navy, said that when he entered the navy in 1878 the rate of sickness was 47 per 1000, to-day it was only 25, and the invalid rate was now 15 as against 35 in 1878 In the latter year the death-rate in the navy was 6 per 1000, whereas to-day it was 2 The improvement was due to sanitation and the education of the men, for every sailor in the service attended lectures on personal hygiene

Sir ALFRED KEOGH emphasised the importance of the health of the troops in the maintenance of an army's fighting strength and said that Colonel Horrocks was the officer most responsible for the very satisfactory health of our army now in France, and his record extended back many years, the abolition from Malta of undulant fever having been due to him Formerly there were in that island 600 or 700 men stricken with that disease, and hospitalisation alone cost £15 000 a year To-day there was no fever Colonel Horrocks had also done much steady work in improving the sanitation of camps and barracks

Colonel SANDWITH then delivered a lecture on

The South African and the Russo-Japanese Campaigns

He said the Japanese army medical officers held that there were three grades of illness (*a*) comprising wounds or disease caused by hardships and exposure incidental to warfare, (*b*) diseases accidents, or injuries to which the soldier might succumb in circumstances beyond his control; and (*c*) diseases brought about by disobedience to orders, immorality, the eating of unwholesome food and the drinking of dirty water The victim of the latter received no sympathy Before the Russo-Japanese War the individual Japanese soldier was made to understand how largely his health contributed to the fighting efficiency of the army, and this was an important factor in the avoidance by that nation of serious epidemic disease during the campaign. This lesson had had its good effect on our own army, and the French admired the British troops in this war for their hygienic observances No illness so dogged the steps of an army as did typhoid fever For many years water contamination was thought to be the cause but epidemics had occurred where the water supply was excellent, and dust and flies had obviously to be blamed He particularised the case of Quetta which had an admirable water supply A striking instance was that which occurred in the camp at Modder River in the South African campaign The winds covered the food with grit, and flies multiplied rapidly The first case of typhoid fever was recognised on Dec. 18th 1900 and by the end of that month 18 cases had been admitted into hospital The Highland Brigade camp suffered the least because it was in a wind protected locality. There was also great danger from the handling of food by typhoid carriers, some of whom had had the disease so slightly that it escaped recognition, especially in view of the necessary huddling of the men together in quarters during war time The typhoid death-rate in civil life varies from 5 per cent to 20 per cent; among armies in war time the rate is much higher owing to the absence of the best nursing facilities In the South African War we lost 8022 from this disease 19 454 were invalided and 30 208 were either returned to duty or otherwise discharged The mortality from typhoid fever in the war exceeded in number that of the men killed in action Each the arm encased in plaster Sinuses leading to the head of the bone formed, and necessitated a second operation The previous incision was opened and the plate with three screws removed The capsule was then opened and the head of the bone disarticulated Careful search failed to reveal the head of the nail The sinus in the bone was therefore enlarged and the nail grasped at its point with forceps and pulled out The sinus was curetted and drained The patient recovered and had good motion in all directions except elevation In the second case a coloured girl, aged 3 years, had separation of the lower humeral epiphysis An attempt at reduction by hyperextension and flexion under ether was attended with indifferent success An incision was made over the olecranon process down to the bone and the fragments were delivered after much trouble As no surface presented extra articularly through which nails could be passed and the fragments did not remain in apposition when released two small wire nails were passed from the articular surface through the epiphysis into the shaft Three weeks after the operation there was some motion in the joint The final result cannot yet be stated, but Professor Winslow believes that without operation function would have been seriously impaired He claims that his cases show that intra articular fractures which cannot be otherwise treated should be screwed or pegged from the articular surface, that the joint tolerates a foreign body provided infection does not occur, and that this method offers a better prospect than leaving the fragments in bad alignment

---

[1] A report of the first lecture appeared in THE LANCET of Jan. 23rd, p. [illegible]

ANÆSTHESIA IN GOITRE OPERATIONS

THE problem of safe and satisfactory anæsthesia in operation for goitre may present more difficulty to the anæsthetist than is met perhaps in any other class of case There are, of course, plenty of instances where in the absence of respiratory difficulty from pressure and of all symptoms of hyperthyroidism the choice and administration of the anæsthetic are at least as simple as in any other operation in the neighbourhood of the neck When, however, there is narrowing of the trachea from pressure or still more when there are marked tachycardia and other indications of hyperthyroidism, then the question becomes an anxious one Still more, needless to say, is this the case when the patient presents to a marked degree the signs and symptoms of actual exophthalmic goitre The mechanical difficulty in these cases may be regarded as that which is most easily obviated It is, of course, true that any dyspnœa due to mechanical narrowing of the trachea is liable to be increased during anæsthesia by swelling of mucous membrane and congestion of vessels as well as by spasm The avoidance of all closed methods of administration, however, the preliminary injection of atropine, and a gradual induction usually result in anæsthesia without any increased difficulty in such cases The mechanical obstruction may be overcome with even greater certainty by the insufflation of ether through a tracheal catheter should the passage to this not be of itself a too difficult achievement A much more difficult problem than the mechanical one is presented by the nervous condition of some of these patients and by their tendency to syncope during operation, or to an increase afterwards of the tachycardia till the heart finally runs down exhausted by its own rapidity We do not know the essential cause of this fatal tachycardia, and cannot even declare positively that it is partly attributable to anæsthesia and not wholly to the effect of manipulation of the thyroid gland with increased entry of its secretion into the circulation Dr W S Bainbridge, who has recently discussed the question before the American Association of Anæsthetists, believes that fatalities of the kind described are more apt to occur after operations done during general than after those done with local anæsthesia. His preference for local agents in this class of case has the authoritative support of Kocher The disadvantage of the presence of consciousness on the part of these sensitive, excitable patients is, however, not to be overlooked, and indeed Dr Bainbridge himself points out that operating with local anæsthesia throws great strain upon the surgeon, and not infrequently is associated with discomforts, if not with pain, on the patient's part These things, however, cannot be allowed to weigh seriously against any marked superiority from the point of view of safety, and if it can be clearly shown from comparing large numbers of cases that general anæsthesia involves the occurrence of more fatalities than local, then preference should surely be given to the latter method The use of rectal and of infusion methods is obviously applicable to this class of case The considerable inconvenience of the former and the oozing associated with the latter are, we imagine, their chief detriments Moreover, in the case of infusion, any considerable addition to the amount of fluid in the circulation would not appear to be without detriment in the type of patient under consideration. Crile's well known process of "stealing the thyroid" may meet the temperamental difficulties of the patient very well, but we cannot believe that sufficient calm cannot be induced, if it is possible at all, by quiet, tactful, and deliberate handling of the patient at the time of induction of anæsthesia without rehearsals

THE ETIOLOGY OF CONGENITAL HYDROCEPHALUS

THE old Neapolitan custom of treating chronic hydrocephalus by mercurial friction and the often favourable result obtained thereby, very justly gave rise to the suspicion that this morbid condition might be due to hereditary syphilis It was rarely possible, however, to adduce evidence of specific infection in the parents Recent biological methods have now proved that almost invariably chronic hydrocephalus owes its origin to parental syphilis Former observers had already shown that among those diseases to which the congenital syphilitic is subject hydrocephalus occupies the chief place after idiocy and imbecility, but when Wassermann's test was applied to the etiology of hydrocephalus negative results seemed to discountenance any relation between it and hereditary syphilis In 1912 Cannata, having made observations on 12 cases of congenital hydrocephalus came to the conclusion that hereditary syphilis plays a more important part in the pathology of chronic internal hydrocephalus than has usually hitherto been admitted In a new periodical issued by the medical staff of the lunatic asylum at Catanzaro, under the direction of Professor Frisco, two well marked and instructive cases are recorded in one the Wassermann reaction was positive both in the mother and child who was second born following a premature birth of a dead fœtus In the second case the reaction was positive in father, mother, and child to wear the prescribed uniform Surgeon Captain Thomas Duncan Greenlees (late Grahamstown (South Africa) 1st City Volunteers) to be Major (temporary) Captain William E Rielly, from 2nd London Field Ambulance, to be Captain Lieutenant John B Bate to be Captain (temporary) Lieutenant James P N Casey, from 1st London Field Ambulance, and Hugh Gilbert Bruce to be Lieutenants

ORDER OF ST JOHN OF JERUSALEM

The King has sanctioned the promotion to Knight of Grace of Lieutenant-Colonel William Ernest Jennings, I M S

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last census, 8172 births and 6259 deaths were registered during the week ended Saturday, Jan 23rd The annual rate of mortality in these towns, which had been 21 3 19 4, and 18 8 per 1000 in the three preceding weeks, further fell in the week under notice to 18 0 per 1000 of their aggregate population, estimated at 18,134 239 persons at the middle of 1914 The annual death rate last week ranged from 6 6 in Eastbourne, 8 0 in Ilford, 9 6 in Coventry, 10 5 in Acton, and 10 9 in Southport and in Blackpool, to 25 3 in Gateshead, 27 1 in Cambridge, 31 9 in Merthyr Tydfil, 36 3 in Great Yarmouth, and 37 5 in Gillingham

The 6259 deaths from all causes were 286 fewer than the number in the previous week, and included 479 which were referred to the principal epidemic diseases, against numbers declining from 575 to 454 in the three preceding weeks Of these 479 deaths, 206 resulted from measles 93 from whooping cough 83 from diphtheria, 62 from infantile diarrhœal diseases 23 from scarlet fever, and 12 from enteric fever, but not one from small pox The mean annual death rate from these diseases was equal to 1 4 or 0 1 per 1000 more than in the previous week The deaths attributed to measles, which had been 269, 183 and 195 in the three preceding weeks, further rose to 206 last week and caused the highest annual death rates of 2 1 in Newcastle-on Tyne, 2 2 in Ealing, in Wolverhampton, and in Preston, 2 5 in Merthyr Tydfil, 3 1 in Gateshead, 3 2 in Rotherham, 3 3 in Grimsby 3 7 in Plymouth, and 4 0 in Wigan The deaths referred to whooping-cough, which had been 80 93, and 76 in the three preceding weeks rose to 93 last week, and included 22 in London, 8 in Bristol, 5 each in Willesden Liverpool, and Merthyr Tydfil, 4 in Stoke-on Trent and 3 each in Gloucester, Nottingham, Newcastle-on Tyne, and Cardiff The fatal cases of diphtheria which had been 89, 77, and 63 in the three preceding weeks rose to 83 last week, of these 8 each occurred in London and Birmingham, 7 in Bristol 5 each in Manchester and Sheffield, 4 each in Warrington and Leeds, and 3 each in Bradford and Stockton on Tees The deaths of infants (under 2 years) attributed to diarrhœa and enteritis which had been 86, 84, and 75 in the three preceding weeks, further declined to 62 last week and included 14 in London 8 in Birmingham, and 3 each in Preston and Gateshead The deaths referred to scarlet fever which had been 31 35 and 34 in the preceding three weeks fell to 23 last week of which 5 occurred in Liverpool and 4 in London The fatal cases of enteric fever which had been 20 15, and 11 in the three preceding weeks, were 12 last week, and included 2 in London

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily declined from 5035 to 3952 in the eight preceding weeks, had further fallen to 3836 on Saturday last 308 new cases were admitted during the week against 436 321, and 338 in the three preceding weeks These hospitals also contained on Saturday last 1643 cases of diphtheria, 109 of measles 56 of enteric fever and 35 of whooping-cough but not one of small pox The 1597 deaths from all causes in London were 104 fewer than in the previous week and corresponded to an annual death rate of 18 4 per 1000 The deaths referred to diseases of the respiratory system which had been 562 497 and 472 in the three preceding weeks further fell to 417 in the week under notice and were 3 below the number in the corresponding week of last year

Of the 6259 deaths from all causes in the 96 towns 252 resulted from different forms of violence and 545 were the subject of coroners inquests while 1667 occurred in public institutions The causes of 62 or 1·0 per cent. of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest All the causes of death were duly certified in Leeds Bristol West Ham Bradford and Newcastle-on-Tyne Nottingham and in 59 other smaller towns Of the 62 uncertified causes 13 were registered in Birmingham, 6 in Liverpool 4 each in Stoke-on Trent, Preston, and Gateshead, and 2 each in Ilford, Dudley, Bootle, Bolton, and Manchester

HEALTH OF SCOTCH TOWNS

In the 16 largest Scotch towns with an aggregate population estimated at 2,345,500 persons at the middle of this year, 1258 births and 977 deaths were registered during the week ended Saturday, Jan 23rd The annual rate of mortality in these towns, which had been 20 5, 24 5, and 22 8 per 1000 in the three preceding weeks, further declined to 21 7 per 1000 in the week under notice Among the several towns the death rate ranged from 12 5 in Motherwell, 14 2 in Coatbridge, and 15 2 in Falkirk, to 25 3 in Aberdeen, 25 9 in Dundee, and 29 4 in Perth

The 977 deaths from all causes were 50 fewer than in the previous week, and included 98 which were referred to the principal epidemic diseases, against 117 and 92 in the two preceding weeks Of these 98 deaths, 58 resulted from whooping-cough 16 from scarlet fever, 8 from diphtheria, 8 from infantile diarrhœal diseases, 7 from measles, and 1 from enteric fever, but not one from small pox. The mean annual death rate from these diseases was equal to 2 2, against 1 4 per 1000 in the large English towns The deaths attributed to whooping-cough, which had increased from 28 to 56 in the four preceding weeks, further rose to 58 last week, of which 37 occurred in Glasgow, 11 in Dundee, 6 in Edinburgh, and 2 in Motherwell The deaths referred to scarlet fever, which had been 17, 13 and 9 in the three preceding weeks, rose to 16 last week, and included 8 in Glasgow and 3 each in Aberdeen and Paisley The fatal cases of diphtheria, which had been 14, 21 and 10 in the three preceding weeks, further fell to 8 last week, of which 4 were registered in Glasgow and 2 in Edinburgh The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 11, 17, and 7 in the three preceding weeks were 8 last week, and included 3 in Glasgow The 7 deaths referred to measles comprised 6 in Dundee and 1 in Glasgow, and were equal to the number recorded in each of the two preceding weeks The fatal case of enteric fever was registered in Glasgow

The deaths referred to diseases of the respiratory system, which had steadily increased from 154 to 275 in the six preceding weeks fell to 238 in the week under notice, 30 deaths resulted from different forms of violence, against 32 and 35 in the two preceding weeks

HEALTH OF IRISH TOWNS

In the 27 town districts of Ireland with an aggregate population estimated at 1 212 380 persons at the middle of this year, 665 births and 557 deaths were registered during the week ended Saturday, Jan 23rd The annual rate of mortality in these towns, which had been 27 8, 26 5, and 24·4 per 1000 in the three preceding weeks, further fell to 24·0 per 1000 in the week under notice The annual death rate last week was equal to 27 7 in Dublin (against 18 4 in London and 22 2 in Glasgow), 20 2 in Belfast 37 4 in Cork, 19·0 in Londonderry, 12 2 in Limerick, and 26 6 in Waterford while in the 21 smaller towns the mean death rate was 21 9 per 1000

The 557 deaths from all causes were 11 fewer than the number in the previous week and included 35 which were referred to the principal epidemic diseases, against 38 and 48 in the two preceding weeks Of these 35 deaths, 15 resulted from measles 9 from whooping-cough, 4 from infantile diarrhœal diseases, 3 from scarlet fever, 2 from enteric fever and 2 from diphtheria, but not one from small pox. The mean annual death rate from these diseases was equal to 1 5, against 1 4 and 2 2 per 1000 in the English and Scotch towns respectively The deaths attributed to measles which had been 9 6 and 12 in the three preceding weeks further rose to 15 last week and included 11 in Belfast The deaths referred to whooping-cough, which had been 7 11 and 10 in the three preceding weeks were 9 last week and comprised 6 in Dublin, 2 in Belfast and 1 in Cork The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had increased from 9 to 14 in the four preceding weeks fell to 4 last week and included 2 in Dublin The 3 deaths attributed to scarlet fever occurred in Belfast the deaths from diphtheria in Dublin and Sligo and the fatal cases of enteric fever in Dublin and Limerick

The deaths referred to diseases of the respiratory system, which had been 162 139, and 164 in the three preceding weeks, fell to 137 in the week under notice Of the 557 deaths from all causes, 177 or 32 per cent occurred in public institutions and 8 resulted from different forms of violence The causes of 28 or 5·0 per cent of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest in the English towns the proportion of uncertified causes did not exceed 1·0 per cent case was under treatment an average of 56 days, and was necessarily a source of danger during the whole of that period The conditions encountered by the army were greatly aggravated in the beleaguered city of Ladysmith, where the half starved garrison had to draw its water supply from a river known to be contaminated During the 120 days of siege there were 1280 cases of typhoid fever, with 360 deaths, and 1841 cases of dysentery, with 105 deaths When our troops entered Bloemfontein they found two churches filled with Boers suffering from typhoid fever During the forced marching tents had to be pitched for the relief of about 130 men who collapsed from the effects of the heat On Feb 16th one brigade was marching and fighting for more than 15 hours When the battle of Paardeburg began the men had been marching 24 hours, during which some had nothing to eat The fighting lasted 12 hours When a week later, Cronje surrendered, among his force were 160 sick and wounded including 10 cases of enteric fever In 20 weeks from March to July there were 1134 deaths in Bloemfontein, of which 85 per cent were due to typhoid fever War could never be waged on land by hygienic methods, the supreme object was to defeat the enemy, but in anti typhoid inoculation we had now a means of circumventing the danger It was very gratifying to find that the soldiers were becoming more and more convinced of the efficacy of this preventive measure, and the vast majority of those on active service were now so protected Typhoid fever was found to be five or six times as common in the non inoculated as in the inoculated At Avignon (France) in 1912 typhoid fever broke out in barracks containing 2053 men, of whom 1366 were protected Of the 687 unprotected there were 155 who had the disease and 21 died while among the protected there was not one case In 1913 the French Senate resolved that the protective treatment should be made compulsory throughout the army In Canada, among the camps of the Canadian Pacific Railway, 3500 men were protected, and only two cases of typhoid fever occurred, while among 4500 non protected men there were 228 cases In the face of such facts it was difficult to understand those who were trying to persuade the soldier not to submit to it The lecturer proceeded to deal next with the case of dysentery and cholera, describing the course of these diseases and their method of spread, remarking that in the South African War there were 38,108 cases of dysentery,[2] the chief source having been the water supply In her war with China Japan had 155 140 cases of dysentery, with 38 000 deaths On Oct 22nd last 98 cases of cholera were reported in Austria and 231 in Hungary Cholera had also appeared in some of the Russian towns Dr Fleming and others were sent from this country to the Russian side to ascertain what particular kind of cholera bacillus was present, they had now returned and were, he believed engaged in preparing a vaccine He had words of warm commendation to those British officers, including Sir Francis Wingate, who showed such heroism in combating the Egyptian cholera epidemic In the Greek army the mortality among unvaccinated cholera patients was 275 in each 1000 cases of the disease, in the vaccinated 102 per 1000 cases The British authorities were providing in every possible way against the invasion of cholera among our troops The lecture was illustrated by very informing slides, including photo micrographs of disease bacilli

Sir FREDERICK TREVES, in proposing a vote of thanks to Dr Sandwith emphasised what he said regarding the attitude to be adopted towards typhoid fever in war The education of the soldier on the question was most important The second line of attack was the improvement of the sanitary condition of the army Speaking as a member of the Sanitary Committee at the War Office he could say there had never been a time in the history of any campaign when the wounded or sick soldier had been better looked after But this was not all, for even medical men versed in every detail of personal care and sanitation had, when in charge of typhoid camps, contracted the disease A further precaution was necessary—namely, inoculation Since the present war began there had been in the British Expeditionary Force only 212 cases of typhoid fever 201 of them in unprotected men for 173 of them had not been inoculated at all, only 11 of this number had been fully inoculated Not one inoculated man in the whole force had died from the disease In the face of such facts those who tried to persuade the men not to submit to the measure were playing into the hands of the enemy He also alluded with much satisfaction, to the universality of motor transport in the present operations near the front At the actual firing line, however, horse transport could not be dispensed with

The vote of thanks to the lecturer was very heartily accorded

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

THE following appointments have been notified —Staff Surgeon N B V Jacob to the *Pembroke* additional, for disposal Temporary Surgeons H O Blanford to the *Roxburgh* S L Harke to the *Impregnable*, and A M Gray to the *Woolwich*

The undermentioned have been granted temporary commissions as Surgeons in His Majesty's Fleet —John Grandisson Watkins, Purser Davies, Lionel Frederick Strugnell and David Sutherland

The following Surgeon Probationers, R N V R, have been entered as Temporary Surgeons, R N —H G Moser and L S Fry

ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Probationers G Pearson to the *Blake*, additional, for the *Goldfish* and W L Hunter

ROYAL ARMY MEDICAL CORPS

Honorary Major Guy N Stephen to be temporary Lieutenant-Colonel (dated Jan 10th)

To be temporary Captains —Dated Dec 29th, 1914 Charles Edward Forbes Mouat Biggs Dated Jan 4th Robert Sturgeon Cocke

Peter Macdiarmid is granted temporarily the honorary rank of Captain (dated Jan 27th)

To be temporary Lieutenants —Dated Dec 9th, 1914 Arthur Vernon Stocks Dated Dec 18th, 1914 James Stewart Hall and Hugh Llewellyn Apthorp Dated Dec 22nd 1914 James Edward Cook Dated Dec 29th, 1914 Frederick Pearson Fisher Dated Dec 31st, 1914 John Samuel Martin, John Gibson, and Ronald Bute Macfie Dated Jan 4th Arthur Hyde Greg Dated Jan 5th James Edmund Rutherford Dated Jan 6th Charles Edward Pepper Dated Jan 7th James Donald Finlay, Andrew Grant George Douglas Sherwood, Thomas Lister Llewellyn, Bernard Creasy Evens John Laing Annan Wilfred Garton, George Henry Steven Dudley Forde Albert Ernest Hodgson James Joseph Keirans, and John Lang Dated Jan 8th Henry Percy Harpur and James Fettes

SUPPLEMENTARY TO REGULAR UNITS OR CORPS

Royal Army Medical Corps

The undermentioned to be Lieutenants (on probation) —Francis Antrobus Duffield, John Joseph Molyneaux Frederic Sanders George Stephen Pirie Edwin John Bradley, Frank Oppenheimer, James Walker Wood, and George Macdonald Scott

TERRITORIAL FORCE

Honourable Artillery Company

"A" Battery 1st City of London Horse Artillery Surgeon Lieutenant Colonel and Honorary Surgeon Colonel Richard J Reece is seconded

Royal Army Medical Corps

1st Wessex Field Ambulance Walter Fitzpatrick (late Captain, Royal Army Medical Corps Territorial Force) to be Captain (temporary)

2nd Highland Field Ambulance Lieutenant James A Stephen to be Captain (temporary) Thomas Stewart Slessor to be Lieutenant

3rd Southern General Hospital Lieutenant Colonel Horatio P Symonds resigns his commission on account of ill health

2nd West Riding Field Ambulance Hartas Foxton to be Lieutenant

1st London (City of London) Sanitary Company Robert Robison to be Lieutenant

West Lancashire Casualty Clearing Station Lieutenant William N W West Watson, from 3rd West Riding Field Ambulance to be Lieutenant

West Riding Casualty Clearing Station David Rutherford Cramb to be Lieutenant

Sanitary Service Thomas Hamilton Ward (late Lieutenant, Royal Army Medical Corps Territorial Force) to be Captain whose services will be available on mobilisation

Attached to Units other than Medical Units —Major Alexander Leitch resigns his commission on account of ill health, and is granted permission to retain his rank and

[2] THE LANCET Sept 5th 1914 p 63[illegible]

VITAL STATISTICS OF LONDON DURING DECEMBER, 1914

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the 10 diseases specified in the table was equal to an annual rate of 9 2 per 1000 of the population, estimated at 4,516,612 persons in the middle of last year, in the three preceding months the rates were 11 6, 14·0, and 12 5 per 1000 respectively The lowest rates last month were recorded in St Marylebone, Hampstead, Hackney Holborn, Poplar, and Bermondsey, and the highest rates in Hammersmith Fulham, the City of London, Bethnal Green, Stepney, and Deptford The prevalence of scarlet fever showed a marked decline from the high numbers in the two preceding months, the greatest proportional prevalence of this disease last month was recorded in Hammersmith, Fulham, Stepney, Deptford, and Lewisham The Metropolitan Asylums Hospitals contained 4431 scarlet fever patients at the end of last month, against 4561 and 4956 at the end of the two preceding months, the weekly admissions averaged 445, against 618 and 661 in the two preceding months Diphtheria also was less prevalent than in either of the two preceding months, this disease was proportionally most prevalent last month in Hammersmith Fulham, Finsbury, the City of London, Shoreditch Bethnal Green, Stepney, and Woolwich There were 1653 diphtheria patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 1459 and 1630 at the end of the two preceding months the weekly admissions averaged 177 against 213 and 247 in the two preceding months The prevalence of enteric fever, which had shown a decline in November increased again last month, the greatest proportional prevalence of this disease was recorded in Chelsea, the City of Westminster St Marylebone, the City of London, Shoreditch, and Stepney The number of enteric fever patients under treatment in the Metropolitan Asylums Hospitals, which had been 65 and 63 at the end of the two preceding months, rose again to 68 at the end of last month, the weekly admissions averaged 10, against 11 and 8 in the two preceding months Erysipelas was proportionally most prevalent in Fulham, Finsbury Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, Deptford, and Woolwich The 24 cases of puerperal fever notified during the month included 5 in Fulham 3 in Camberwell, and 2 each in Hampstead St Pancras, Islington, Stepney, Southwark, and Wandsworth The 5 cases of cerebro-spinal meningitis included 2 in Lambeth, where 3 of the 7 cases of poliomyelitis also occurred

The mortality statistics relate to the deaths of persons actually belonging to the several boroughs the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided the death rates from all causes are further corrected for variations in the sex and age constitution of the populations of the several boroughs During the five weeks ending Jan 2nd the deaths of 7246 London residents were registered, equal to an annual rate of 16 7 per 1000, in the three preceding months the rates were 15 5 14 1 and 14 6 per 1000 respectively The death rates last month ranged from 12·0 in Wandsworth, 13 3 in Hampstead 13 5 in Lewisham 13 8 in Camberwell, 14 3 in St Marylebone, and 14 4 in Battersea to 19 6 in Southwark 19 7 in Greenwich, 20 5 in Shoreditch 20·7 in Poplar 20·9 in Stepney 21 7 in Holborn and 23 1 in Finsbury The 7246 deaths from all causes included 542 which were referred to the principal infectious diseases, of these, 224 resulted from measles 47 from scarlet fever 101 from diphtheria, 49 from whooping cough 9 from enteric fever and 112 from diarrhœa and enteritis among children under 2 years of age No death from any of these infectious diseases was recorded last month in Hampstead among the other boroughs they caused the lowest death rates in Chelsea, Stoke Newington, the City of London Wandsworth and Lewisham and the highest rates in Hammersmith Fulham Hackney Southwark Stepney Shoreditch, and Bethnal Green The 224 deaths from measles were 35 above the corrected average number in the corresponding period of the five preceding years, this disease was proportionally most fatal last month in Hammersmith Hackney Bethnal Green Southwark and Lambeth The 47 fatal cases of scarlet fever were 23 in excess of the corrected average the greatest proportional mortality from this disease being recorded in Fulham Stoke Newington Finsbury and [illegible] The 101 deaths from diphtheria were 48 above the corrected average number, this disease was proportionally most fatal in Hammersmith Fulham St Marylebone Shoreditch Bethnal Green Stepney Deptford and Woolwich The 49 fatal cases of whooping-cough were 19 fewer than the corrected average the highest death rates from this disease last month were recorded in Hammersmith, Fulham, Holborn and Deptford The 9 deaths from enteric fever were 6 below the corrected average, and included 2 in the City of Westminster The mortality from diarrhœa and enteritis among children under 2 years of age was proportionally greatest in Paddington, Hackney, Shoreditch, Stepney, Poplar, Southwark, and Bermondsey In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases was 25 per cent above the average

---

IRISH MEDICAL ASSOCIATION AND THE CASE OF MR NATHANIEL MAYNE.—At a meeting of the Council of the Irish Medical Association held last week a resolution was passed unanimously, protesting against the attempt of the governing body of the County Longford Infirmary to dismiss Mr Mayne from the office of surgeon to the infirmary, and declaring that in the opinion of the Council Mr Mayne had acted properly and prudently and in accordance with the rules of the institution

ROYAL MEDICAL BENEVOLENT FUND—The annual general meeting of subscribers to this fund will be held at 15 Wimpole street, W, on Tuesday, Feb 9 h, at 4 P M The chair will be taken by the President, Sir John Tweedy, LL D, F R.C S Eng —At the last meeting of the committee 22 cases were considered and grants amounting to £202 voted to 19 of the applicants An annuity of £20 was also made to one of the applicants The following is a summary of the cases relieved —

Wife aged 48 of M R.C S Eng who practised at Chesham Was deserted by her husband in 1905 Has three children the youngest at Epsom College others at school Eyesight defective Only income about £25 per annum Previous relief £14 Voted £12 in 12 instalments —Widow aged 74 of M R C S Eng who practised at Braintree Lives with married son who has large family and only a small income. No income of her own and unable to work. Was elected to an annuity of £20 per annum Previously relieved £2.—Widow aged 66 of M R C S Eng who practised at Heywood Lancs. Has acted as cook and nurse but finds it difficult in consequence of age to obtain work. Previous relief £2. Voted £12 in 12 instalments —Widow aged 30 of M B., B S Lond R A.M C who was killed at the front Since husband's death has undergone severe operation and quite unable to work at present Only income War Office pension Voted £15 towards convalescence.—Widow aged 67 of M D St And and F R C S Eng who practised at Kidderminster Present distress caused by the depreciation of securities and the death of her sister with whom she lived Health bad Voted £10 in two instalments.—Widow aged 34 of M R C S Eng who practised at Swansea and died in 1914 Left her totally unprovided for Right side paralysed One daughter aged 6 years Lives with mother whose means are very limited Voted £12 in 12 instalments —Widow aged 62 of L.R C S Edin. who practised in Brixton Present distress caused by depreciation of her dividends and being unable to let her furnished house Health too bad to allow her to work Voted £10 in two instalments —Daughter aged 59 of M R C.S Eng who practised at Battle Unable to work owing to chronic rheumatism Lives with sister who is also badly off Relieved 31 times £242. Voted £12 in 12 instalments —Widow aged 77 of M.R C S Eng who practised at Leamington Tries to earn a little by taking in lodgers but owing to age not able to do much. Has the Old Age Pension Has seven children none of whom can help. Relieved three times £36. Voted £12 in 12 instalments —Widow aged 59 of L R C P Irel who practised at Buckley Health very indifferent Only income a pension from another charity of £25 Relieved seven times. £34 Voted £12 in 12 instalments —Daughter aged 31 of M R C S Eng who practised at Wolverhampton Suffers from Graves's disease and unable to undertake any permanent work Relieved seven times £46. Voted £12 in 12 instalments —Widow aged 58 of M R.C S Eng who was an annuitant of the Fund Eldest son used to keep the home but has joined the army and unable to do much Other son's earnings very much reduced Relieved once £10 Voted £2, with leave to apply again.—Daughter aged 62, of M R.C S Eng who practised at Watford. Health bad. Only income £20 from another charity and a little from sewing Has to assist to keep an invalid brother Relieved eight times £93 Voted £15 in 12 instalments —Widow aged 58 of M R C S Eng who practised at Sydney N S W Has own house, which is heavily mortgaged and has been empty for five years Only daughter a professional singer but owing to the war cannot obtain engagements Relieved three years ago £10 Voted £10 in two instalments —Daughter aged 70 of M.R.C S Eng who practised at Stoke Newington Lives with two sisters and they try to make a living by taking in boarders but in consequence of the war have lost several foreign boarders Relieved twice £24 Voted £18 in 12 instalments and recommended for an annuity —Widow aged 62 of M R.C S Eng who practised at Maidstone Earns her living by taking in paying guests but in consequence of the war has lost two Only income from friends which is uncertain about £20 Relieved four times £31. Voted £12 in 12 instalments —Daughter aged 67 of M R.C S Eng who practised at Greenwood Hantsville Health very bad and lost all her money invested in an apartment house Earns a little by needlework and friends provide food Relieved four times £[illegible] Voted £12 in 12 instalments —Widow aged [illegible] of L S A who practised at [illegible] Lost all capital in investments Takes in a boarder when she can get one and earns a little by needlework Relieved twice £24 Voted £12 in 12 instalments

Contributions may be sent to the honorary treasurer Dr Samuel West 11 Chandos street, Cavendish square, W —Queen Amélie will preside at the annual general meeting of the Royal Medical Benevolent Fund Guild at the Royal College of Physicians of London, on Thursday, Feb 4th, at 3 30 o clock.

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING DECEMBER, 1914.

(Specially compiled for THE LANCET.*)*

Cities and Boroughs	Estimated population in the middle of 1914	Notified Cases of Infectious Disease: Small pox.	Scarlet fever	Diphtheria.*	Typhus fever	Enteric fever	Other continued fevers. Jan 7th, 1915, and that he had continuously practised the same either in the United Kingdom or elsewhere for a period of not less than ten years immediately preceding Jan 7th, 1915

Application should be made to the Registrar for a form for the use of Belgian practitioners seeking registration Belgian practitioners who fulfil the prescribed conditions may thereupon, without further examination, be inscribed in the British Register, and acquire all the rights and privileges of duly qualified British practitioners

The documents, the prescribed fee (Five pounds), and the cost (One shilling) of the Government stamp should be transmitted to the Registrar of the General Medical Council, 299, Oxford street, London, W —I am, Sir yours faithfully,

A J COCKINGTON,

Jan. 27th 1915 Acting Registrar

THE PREVENTION OF FROST-BITE

To the Editor of THE LANCET

SIR,—There are some points in the prevalence of frost bite affecting the Expeditionary Force which are worthy of careful consideration with a view to prevention. In the first place it is not mere cold that produces frost bite. The attacks with our soldiers are limited almost entirely to the feet, from the minor degrees in the form of chilblains through all the further stages up to positive gangrene If we look to the accounts of Arctic and Antarctic experience we find frost bite mostly in exposed parts—face and hands—and chiefly accounted for by the prevalence of wind in association with low temperature When the feet have been attacked it has mostly been in association with wet In the trenches, in which frost bite is almost exclusively met with the conditions present are those of water or mud slush with low temperature, a temperature, however, far above the highest met with in the Arctic or Antarctic winters Further conditions to which frost bite is attributable are long maintenance of the upright posture with general fatigue and lowered vitality from exposure It is obvious, however, that amongst the important contributory causes must be mentioned (1) any tightness of leg gear causing a constriction of circulation, and (2) ill fitting boots having the same effect If the precautions mentioned by Mr A W Mayo Robson as laid down in the Army Medical Regulations be observed these latter causes will be obviated[1] No doubt sound and more or less water tight boots are of some value but it practically is the case that the soldiers are ofttimes well over their boots in water or slush, so that the soundness of the boot in this respect is of little avail It has been suggested that the men in the trenches should wear water tight thigh boots something after the fashion of those used by our sewer inspectors but it should be remembered that the men must be fit at any moment for skirmishing, quick marching or hand to hand fighting in all of which foot agility is of the utmost importance In a charge or bayonet encounter foot work is as important as in boxing or fencing and to handicap feet and legs by cumbrous boot gear would be to sacrifice the men s efficiency and often their lives to the comfort of their feet

Returning to the etiology of this matter I would point out that frost bite in the present war is due (1) to the feet becoming sodden with water and their circulation and vitality thus depressed, and (2) to long exposure to a considerable degree of cold, a degree, however, to which the dry foot would be resistant In the rational treatment of such cases with a view to prevention it is of the first importance to render the feet less permeable to moisture This indication may be best met by their anointment with some greasy material with low hygroscopic properties It is well known to swimmers that anointing with fatty or oily material enables them to withstand cold, but the value of an application of low hygroscopic power for persons whose feet are passively subjected for hours or days to water or half frozen slush is, perhaps, not sufficiently realised

Mr Squire, of Oxford street, has prepared a foot ointment answering the four requirements (1) resistant to water penetration, (2) mildly stimulating and antiseptic, (3) readiness for use, and (4) not too expensive After a good deal of trouble and investigation he has produced an ointment of purified suet, camphorated and with 5 per cent eucalyptus oil, supplied on the pattern of a shaving stick in a metal case with smooth rounded edges The solid ointment is pushed up from the bottom, and when rubbed over the surface leaves a smooth application of the ointment A special advantage of this ointment is that its absorbing power for water is only 5 per cent, whereas most other greasy materials, such as lard, lanoline, &c, have an absorbent power for water of about 30 per cent Mr Squire has also prepared on the same lines a second ointment from palm oil sufficiently stiffened for the purpose but containing only vegetable ingredients, so as to meet the requirements of our Indian troops, to whom all animal fats are repugnant

A limited trial of the first ointment has given so far satisfactory results but it is, of course, too early to draw practical conclusions Meanwhile "the rain it raineth every day" and the cold is bitter for our officers and men

I am, Sir, yours faithfully,

Portland place W Jan 25th 1915 R DOUGLAS POWELL

FAITH AND ASTIGMATISM

To the Editor of THE LANCET

SIR,—I envy Mr C E Pronger and Mr Ernest Clarke, whose communications have recently appeared in THE LANCET What a happy state of mind to be in to be sure! To be able to cure or relieve headache, neuralgia, sleeplessness, fits, and a tendency to insanity and suicide, *et hoc genus omne*, and all with just a pair of spectacles, cylindrical lenses for choice, varying in strength from half a diopter to one eighth thereof I wish I could do it myself Years ago, when at Wiesbaden, the present Professor Pagenstecher told me that many of the English speaking patients who consulted him, when asked what was the matter replied, "Oh I have astigmatism," so much so that he called it the English complaint They do not seem to be troubled so much with the same affection on the continent, or perhaps their 'Kultur does not extend to the diagnosis thereof It is the lower grades of astigmatism which are said to cause all these dire symptoms, and the uneven contraction of the ciliary muscle, in its effort to equalise matters and overcome this, is the *fons et*

---

ITALY

(FROM OUR OWN CORRESPONDENT.)

The Medical Officers of the Army Reserve.

HERE, as everywhere else, the war is the only subject of real interest. The Italian army is mobilised, and for the extra medical service required the medical officers of the reserve of the 1877-78 classes have been called up. These are professional men, 36-38 years of age, and they are rather indignant that the younger classes should not have been called up before them. They protest, too, at the inferior position in which they find themselves, being allowed only the rank of subalterns whatever their professional attainments may be, and so junior in rank to officers of perhaps 24 years of age; in fact, a professor may find himself junior in rank to, and under the orders of, his own pupil. They find themselves on an equality with and obliged to "tutoyer" young subalterns of the other arms of the service, often 20 years their juniors. The duties of orderly officer fall chiefly upon them. They are losing the practices which they have built up by many years of work, and in return are paid by the Government at the rate of 5.53 lire, or 4s. 6d. per day. They demand that they should be allowed the rank to which the majority of the regular officers of their year have attained, while allowing the latter seniority in such rank. Their grievances seem natural enough; do they find an echo among the largely increased staff of the British Royal Army Medical Corps?

Treatment of Tetanus.

The treatment of tetanus is at this moment a very living question. Il Policlinico (Sez. Prat., anno xxi., fasc. 51) returns once more to its advocacy of Baccelli's treatment, or the method of the Roman school. This consists in the injection, either subcutaneously or intramuscularly, of carbolic acid. Solutions varying in strength from 1 to 5 per cent. were used in the cases quoted in the paper, and the quantity of carbolic acid given in 24 hours varied between 20 and 80 centigrammes. For example, one case was treated by subcutaneous injections of 2 c.c. of a 3 per cent. solution every three hours, increased later to a similar quantity of 5 per cent. solution; another received from 24 to 34 cgm. of carbolic acid in 2 per cent. solution daily; another from 40 to 70 c.c. of 1 per cent. solution per diem intramuscularly. Baccelli's method is said to have given extremely encouraging results up to now among the wounded in France. It is well tolerated and under easy control, and has the great merit of simplicity.

Heliotherapy and the Treatment of Wounds.

The wonderful results of sun treatment in the mountain resorts of Switzerland have set the profession in Italy thinking how they may make use of the sun, which is theirs so freely. A start in the right direction was made years ago with the institution of seaside and mountain colonies for delicate children in the summer months. The number of these is on the increase every year, and some of the seaside colonies are now kept open in winter as well as summer. A more direct use of the sun's rays is made by Professor Poli, who has opened this year a sunny terrace overlooking the sea at Genoa for the treatment of children with surgical forms of tuberculosis. An extension of this idea is advocated along the Italian Riviera, and it is claimed that not only are cases of surgical tuberculosis benefited by this heliotherapy but that experiences after the Balkan War have demonstrated beyond doubt the curative effects of the sun's rays in suppurating wounds such as those produced by shrapnel. I fancy that no one would deny that heliotherapy has at least as much effect upon the organisms of suppuration as upon tubercle bacilli, and that most would agree that it is likely to be as safe and quick as, and a great deal more pleasant than, the ordinary methods of treatment of suppurating wounds.

White Slave Traffic.

The Neapolitan police seem to have awakened recently to the flagrant violation of the laws relating to the abuse of young girls. In one night they raided 15 so-called hotels and pensions, restored 73 young girls between the ages of 13 and 19 to their families, and arrested 280 individuals as "sfruttatori di minorenni." The large number of people implicated has made a great impression and drawn public attention to the scandal. Something, it is felt, must be done, and not only in Naples but for all the south of Italy, where the trade in young girls and their export to foreign countries are carried on upon a large scale and with impunity.

BELGIAN PRACTITIONERS AND THE MEDICAL REGISTER.

To the Editor of THE LANCET.

SIR,—In pursuance of the Order in Council dated Jan. 7th, 1915, by which the Medical Act, 1886, was made applicable to the kingdom of Belgium, the Executive Committee of the General Medical Council has passed the following resolution:—

> That so long as the Order in Council of Jan. 7th, 1915, remains in force any person who produces evidence satisfactory to the Registrar that he has obtained the degree of Doctor of Medicine in any of the Belgian Universities of Brussels, Ghent, Liége, or Louvain, and is legally authorised to practise medicine, surgery, and midwifery in Belgium, and who satisfies the Registrar as to the other particulars specified in Section 12 of Part II. of the Medical Act, 1886, shall be entitled to be registered in the Foreign List of the Medical Register.

It is necessary, according to the provisions of the Medical Act, 1886, that any person applying to be registered in respect of the degree of M.D. of any of the above-mentioned universities should produce to the Registrar documents or certificates as follows: (1) Evidence that he possesses the diploma of M.D.; (2) satisfactory evidence of identity; (3) satisfactory evidence of good character; and (4) satisfactory evidence (a) that the applicant is not a British subject, or (b) that being a British subject, the said diploma was granted to the holder at a time when he was not domiciled in the United Kingdom or in the course of a period of not less than five years, during the whole of which he resided out of the United Kingdom, or he was practising medicine or surgery or a branch of medicine or surgery in the United Kingdom on dangerous thing it often leads them to talk a lot of sorry nonsense to their patients

Speaking for myself, I can truly say that my knowledge of physiology has not in any way helped me to lead a healthy life All that the public need know in regard to the preservation of health can be set down in a surprisingly small compass To attempt to disseminate a knowledge of physiology—be it of the generative or any other system—is, in my belief, to mix up the issues in a jangle of mere words, and to obscure what is after all transparently simple I am, Sir, yours faithfully,

Wimpole-street W Jan 23rd 1915 HARRY CAMPBELL

ANATOLE FRANCE AND MORALITY

To the Editor of THE LANCET

SIR,—Mr D Arcy Power s lecture in your issue of to day is admirable in every way, but it is strange to find the works of Anatole France recommended as food for the chaste

The finest stylist of present day French literature is one of the "unmorals," and there are only one or two of his books which do not contain descriptions of intimate amatory relationships, clothed in beautiful but none the less smutty language France is an artist pure and simple, and decidedly not for *la jeune fille* or her brother These remarks apply to the works in the original I have no knowledge of the English translations, but have often heard them described as poor

I am, Sir, yours faithfully,

A. M Ross, M B

Waterfoot near Manchester Jan 23rd, 1915.

EMETINE INJECTIONS IN AMŒBIC DYSENTERY

To the Editor of THE LANCET

SIR,—It may be of interest to record results of the treatment of amœbic dysentery by hypodermic injections of emetine hydrochloride in an out patient practice In the space of 11 months 27 cases were treated and in all cases the symptoms quickly disappeared and the patients were so struck with the result that they came back for more injections even after they were apparently cured We commenced with injections of gr $\frac{1}{3}$ which was given on dispensary days—i e , three times a week—but soon the dose was raised to gr [illegible], gr [illegible], and lastly to gr 1. The majority of cases received gr 1 at each injection with most satisfactory results Gr 1 gave the best and quickest result and no untoward result was ever complained of or observed It is interesting to note that once, when the stock of hypodermic tabloids had run short, a half grain tabloid of emetine was given internally, and when the patient was next seen he reported that on his way home he had severe vomiting and diarrhœa As all were treated as out patients they could not be restricted to a liquid diet All the cases except one were chronic, lasting from one month to four years The number of motions averaged about ten in the 24 hours, two had 16 and one 30 motions All patients showed remarkable improvement after the first or second injection, the hæmorrhage greatly decreased or stopped altogether straining was much less or quite gone the number of motions considerably diminished and the stools became fæcal The pallor disappeared and the pained expression of the face entirely altered after a few injections As a rule no other drug was given, and the majority of cases had no symptoms of the disease after four or five injections In the case which had lasted four years all symptoms disappeared after the third injection of 1 gr emetine hydrochloride Two cases had recurrence of their symptoms and came back for treatment about three weeks after the cessation of the emetine injections One of these cases had a third relapse after six months, when he attended the dispensary for a week, and had three 1 gr injections and was apparently cured We are, Sir, yours faithfully,

LEECHES AND THE WAR

To the Editor of THE LANCET

SIR,—Our country has been for many months suffering from a serious shortage of leeches As long ago as last November there were only a few dozen leeches left in London, and they were second hand

Whilst General Joffre, General von Kluck, General von Hindenburg and the Grand Duke Nicholas persist in fighting over some of the best leech areas in Europe, possibly unwittingly, this shortage will continue, for we have for many years largely depended on importations from France and Central Europe

In November I made some efforts to alleviate the situation by applying to America and Canada, but without success I then applied to India, and last week, owing to the kindness of Dr Annandale, director of the Indian Museum at Calcutta, to the officers of the Peninsular and Oriental Steamship Company, and to Colonel A Alcock, M.D , of the London School of Tropical Medicine, I have succeeded in landing a fine consignment of a leech which is used for blood letting in India It is true that the leech is not the *Hirudo medicinalis* of our pharmacopœias, but a different genus and species, *Limnatis granulosa* Judging by its size, always a varying quantity in a leech, we may have to readjust our ideas as to a leech's cubic capacity, yet I believe, from seeing them a day or two ago, they are willing and even anxious to do their duty They have stood the voyage from Bombay and the changed climatic conditions very satisfactorily, and are in a state of great activity and apparent hunger at 50, Wigmore street London, W

It is true that leeches are not used to anything like the extent they were 80 years ago—Paris alone about 1830 employed some 52 millions a year—but still they are used though in much smaller numbers It may be of some consolation to my fellow countrymen to know that our deficiency in leeches is more than compensated by the appalling shortage of sausage skins in Middle Europe With true German thoroughness they are trying to make artificial ones I am, Sir, yours faithfully,

A E SHIPLEY

Christ's College Lodge Cambridge Jan [illegible]th 1915

THE ASYLUM SERVICE AND BELGIAN REFUGEE DOCTORS

To the Editor of THE LANCET

SIR —It is stated in the *Daily Telegraph* of Jan 20th that the Commissioners hope soon to have Belgian doctors available for employment in the asylum service Both editorially and in many *origo malorum;* where the astigmatism is greater no effort of the ciliary muscle can overcome the irregularity and so it gives up the effort as a bad job and *does not try* Now astigmatism is for the most part *congenital, and one would naturally be* inclined to think that *the ciliary muscle, trained to* this slight unevenness of focusing from its earliest youth, would have got used to it, and that the higher centres would not have been so much upset thereby

My own position is often difficult Being fairly *broad* minded, disinclined to split hairs, and taking an all *round point* of view of things, *I* have gradually *come to the conclusion that* human nature is very complex, that other organs and structures besides the eyes are to be found above the collar bone, and that a pair of spectacles, however rose coloured, will not cure all the ailments to which our flesh is heir Over and over again have I had patients sent to me by physicians—who seem to have swung of late years *from one extreme of the pendulum to the* other—with symptoms of headache and neuralgia, &c, in and about the eyes and their neighbourhood, in whom, after carefully working out their refraction, I have found ⅛ or ¼ diopter of astigmatism, and in view of their symptoms have corrected this and ordered them glasses for constant wear, but I have *so often* failed in relieving the symptoms for which *they consulted me that* I *have got* into the habit of reminding them that the proof of the pudding is in the eating thereof, that the slight error of focus I have discovered may be a factor in the production of their symptoms or not, that if it is, the glasses will be calculated to relieve their symptoms, and in that case they had better continue to wear *them* constantly, but failing relief *after a fair three* months' trial they can leave *them off or only* use them for near work and reading But, *me miserum!* how few have been relieved thereby? Logically, where are we to draw the line? If we are to relieve 1/8 diopter of astigmatism, why not 1/80?

But here, again, another difficulty steps in Personally, I find many—perhaps *most*—patients unable to appreciate *the effect of a* ¼ diopter cylinder, it makes very little, if any, difference to them whether it is held vertically or horizontally, &c What, then, about a cylinder of much less strength? Still, I really believe that some neurotic or neurasthenic people are honestly relieved by weak cylindrical or spherical lenses, and I have in view the case of a *friend—an optician,* strange to say—who *at times* wore weak ¼ diopter cylindrical lenses and claimed he obtained relief thereby I did not prescribe them, he was gouty, very excitable, neurasthenic, the subject of cancer, and by no means a teetotaler It is mainly or entirely in people with a crank *or neurotic* or neurasthenic, who *admit* that these trifling *corrections relieve* them They are people who are easily impressed, and coming into contact with ophthalmic surgeons *of marked personality* after being examined in the dark room and with various weird apparatus and instruments, are told they have astigmatism—a word which, like that *blessed one* Mesopotamia, appeals to their feelings—and that glasses will in all probability relieve or cure them A positive is worth three negatives Thereupon they go off with a prescription with a clock work face and strange figures and hieroglyphics to some optician, who probably makes the remark that the *glasses* the doctor has prescribed are very unusual—as indeed they are, if they are 1/8 diopter cylinders—the result being that they feel something is being done for them, and their symptoms are relieved forthwith, and they think and say they derive much comfort from their glasses—for a time, when they either relapse and go elsewhere, or meanwhile their general health improves, or *they* get married or take up Christian Science or something and all *goes* well, they, at any rate, put down their cure to the oculist But the end is not always so favourable, and the *patient drifts* from one ophthalmic surgeon to another

I have no objection whatever to any oculist impressing a neurotic patient with weak spherical or cylindrical lenses—with such patients, as in love and war, it is fair to adopt almost any means to give them relief—but I do object to anyone thinking or assuming that it is the weakness of the cylindrical or spherical lens that does the trick I have arrived at this conclusion after an experience of over 28 years' considerable practice as an ophthalmic surgeon amongst all sorts and conditions of patients, and the longer I *live* the more convinced *I am of the correctness of the old* Latin maxims, "Media sunt simillima veris" and "In medio tutissimus ibis", and now, to add to my doubts and fears and misgivings, comes this letter from Dr A S Gubb pointing out, as it does, that insomnia is due to many trifling causes, amongst which a loaded rectum plays a not inconsiderable part Really, it will in the future be difficult to know which end of the patient to begin with, and whether a pair of spectacles or a glycerine suppository should have the priority, for many of these patients are the subjects of constipation

I am, Sir, yours faithfully,

Norwich Jan 17th 1915 S JOHNSON *TAYLOR*, M B

THE PHARMACOPŒIAL DOSE

To the Editor of THE LANCET

SIR,—Mr W J Uglow Woolcock's suggestion in his letter in THE LANCET of to day's date relative to unusually large doses in prescriptions of powerful drugs has the great *disadvantage* of acquainting the patient or his friends that an unusually large dose of an active drug is prescribed My practice is to mark the quantity both on the right and left of the drug, and if necessary to underline the quantity marked on the left of the name of the drug

I am, Sir, yours faithfully,

Dublin Jan. 23rd 1915. GEORGE FOY.

PHYSIOLOGY AND MORALITY

To the Editor of THE LANCET

SIR,—In his admirable lecture published *in* your issue of Jan 23rd Mr D'Arcy *Power*, discussing the best *means* of *preventing* the spread of venereal disease, says —

> Knowledge, too is a powerful help The physiology of the generative system is no more a mystery than the physiology of digestion or respiration and there is no reason why it should not be explained in a scientific manner as a part of a course of biology Let the women teach the women

I would ask, in reference to this suggestion, whether a knowledge of the physiology of the generative system has had any influence in preventing the *male* medical student in the past from exposing himself to venereal infection? My experience has been that the smattering of physiology taught to nurses and masseuses is worse than useless. In this, as in other things, a little knowledge is a organisation of the Association should be utilised so as to get into touch with the members of the medical profession all over Scotland Similarly, Dr Ewing put the organisation of the Pharmaceutical Society at the disposal of the committee, so as to press the claims of the Fund on the members of the pharmaceutical profession.

The executive committee was authorised to draw up a circular containing an appeal for contributions and send it to every medical man and pharmacist in Scotland It was announced that up to the present subscriptions amounting to £257 had been received in sums varying from 1 to 20 guineas

Contributions are being received by the treasurers Dr Norman Walker, 7, Manor place, Edinburgh, Dr R McKenzie Johnston, 2, Drumsheugh gardens, Edinburgh, Dr W G Dun, 15, Royal crescent, Glasgow, W, and Mr J Rutherford Hill, Resident Secretary, Pharmaceutical Society, Edinburgh

THE BIRMINGHAM COMMITTEE

The activity of the Birmingham Committee is another feature to which attention may be called A local committee has been formed here with the following as a strong executive Mr Gilbert Barling, M B, F R C S, Vice Chancellor of the University (Chairman), Dr Purslow, President of the Birmingham Branch of the British Medical Association, Mr Christopher Martin, M.B, F R C S, President of the Birmingham Medical Institute, Professor Kauffmann, President of the Midland Medical Society, Dr Lilley, Chairman of the Central Division of the Birmingham Branch of the British Medical Association, Professor Saundby, Sir Thomas Barclay, J P, Mr E W Mann, B Sc, F I C, President of the Birmingham Pharmaceutical Association, Mr J Poole, Mr J A Radford, Mr F Smith, Honorary Secretary of the Birmingham Pharmaceutical Association, and Mr J Wakefield An eloquent circular has been distributed in the district calling attention to the Central Committee which has been formed in London, composed of representative English doctors and pharmacists, to raise money for the immediate relief of members of these professions who are remaining in Belgium, acting in coöperation with a Belgian Committee having similar aims Professor Saundby, Mr Gilbert Barling and Sir Thomas Barclay have joined the Central Committee already The circular of the Birmingham Committee recapitulates the chief points in the speech made by Professor C Jacobs, of Brussels (head of the Red Cross Society in Belgium) at the meeting of the Edinburgh Obstetrical Society on Dec 9th, 1914[1] Professor Jacobs's story loses nothing in terror from condensation and it is not surprising that the Birmingham circular should have met with immediate response

"Subscriptions for any amount," says the circular, "will be gratefully accepted but only actual payments can be acknowledged Cheques or postal orders should be sent to Dr Saundby, 140b, Great Charles street Birmingham or to Mr F Smith, 221 Soho road Handsworth, who are acting as joint honorary treasurers and secretaries They should be drawn in favour of the 'Belgian Doctors and Pharmacists' Relief Fund' and crossed 'Lloyds Bank'"

DANISH UNION OF DOCTORS

[1] The Lancet, Dec [illegible]

letters to your columns it was shown that long before the war was thought of British practitioners in sufficient numbers could not be found to take up these posts owing to their many disabilities Are the Commissioners—or, to give them their latest title, the Board of Control—to import "foreign cheap labour" for this purpose? We all, I hope, sympathise with our Belgian brethren, but it is a serious menace indeed if they are to be used to cheapen the service at the expense of Britishers It may be the asylum service to day, but be sure it will not stop there

I am, Sir, yours faithfully,
Jan 21st 1914 VERB SAP

THE "SHORTAGE" OF DOCTORS

To the Editor of THE LANCET

SIR,—There is one phrase used by Dr Robert R Rentoul in his letter in THE LANCET of Jan 16th which I cannot allow to pass unchallenged—viz, "The school medical officer whose duties are very light" I am a school medical officer to a county education authority My experience as a medical man extends over 17 years, and includes hospital and other institution appointments, a ship's surgeoncy, active service, and private practice at home and abroad

I can definitely state that my present duties are not light, and, further, that the circumstances attendant on professional work—travelling, &c—have never been so continuously arduous

My card is enclosed

I am, Sir, yours faithfully,
Jan 24th 1915 M B

THE medical profession will note with satisfaction that Sir Donald MacAlister, K C B, President of the General Medical Council, and Dr A E Shipley, F R S, Master of Christ's College, Cambridge have been appointed members of the new Royal Commission to inquire into the methods of making appointments and promotions in the Civil Service

CENTRAL MIDWIVES BOARD —A special meeting of the Central Midwives Board was held at Caxton House, Westminster, on Jan 20th, Sir Francis H Champneys being in the chair A number of midwives were struck off the roll, the following charges amongst others having been brought forward The midwife did not wash the patient's external parts with soap and water or swab them with an efficient antiseptic solution before making the first internal examination, as required by Rule E 7 (a), neglecting to provide for the comfort and cleanliness of the patient as required by Rule E 11, that when called to a confinement the midwife did not take with her the appliances and antiseptics required by Rule E 2. That notwithstanding having been warned and with intent to avoid supervision and inspection by the local supervising authority the midwife abstained from notifying the authority of her intention to practise as a midwife, not being scrupulously clean in every way, and not keeping her nails cut short as required by Rule E 1, administering vaginal injections by means of an appliance used for giving enemata contrary to Rule E 2, not taking and recording the pulse and temperature of patients as required by Rule E 13, and making false records of the temperature of patients The placenta and membranes not having been completely expelled within two hours after the birth of the child the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, nor did she hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her in order that this might be immediately forwarded to the medical practitioner as required by Rule E 20 (3), neglecting to stay with the patient until the expulsion of the placenta, as required by Rule E 6 and not keeping the register of cases as required by Rule E 23

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND

THE subscriptions to the Fund have been fairly maintained during the week, the international interest in the Fund has been shown in several ways, and contributions or communications from the colonies and provincial centres have been promising The first meeting of the Scottish Committee, whose personnel was published in THE LANCET and *British Medical Journal* at the beginning of the month, took place last Saturday, and the support at once given is sure to be maintained We announced last week a notable contribution from the doctors in Dunedin, who have sent a lump sum of 100 guineas to the Fund, a donation which has been received with particular pleasure

In the Sheffield district all the medical men have been given notice of a general meeting to be held at the University of Sheffield with the object of forming a local committee

A meeting in aid of the Fund will be held in the College of Medicine, Newcastle on Tyne, on Feb 17th, at 4 P M, when Professor Jacobs, of Brussels, will deliver an address All medical men and pharmacists in the districts of Northumberland, Durham, and Yorkshire are invited to attend, and a local committee will be appointed at the meeting

THE CENTRAL COMMITTEE

A meeting of the central committee was held on Thursday, Jan 21st, at the offices of the British Medical Association, when Sir Rickman Godlee explained the satisfactory results of personal visits to the American Ambassador and Mr Herbert Hoover in respect of the distribution of the parcels of medical stores sent out to Belgium through the medium of the International Committee for Relief in Belgium American assistance is taking a similar form to that devised by the Central Committee Sir Rickman Godlee also reported that a box of instruments which had been selected by Mr Meredith Townsend and himself, with assistance in certain directions, was packed ready for the Belgian doctors, since which definite instructions have been received from the International Committee with regard to the transmission of the box. At this meeting of the Central Committee Dr H A Des Vœux, the honorary treasurer, announced that the total amount subscribed was over £5000, though part of this sum had not been received yet by the treasurer

THE SCOTTISH COMMITTEE

The first meeting of the Scottish Committee was held in the Royal College of Physicians, Edinburgh, on Jan 23rd, Dr J Barlow, President of the Royal Faculty of Physicians and Surgeons of Glasgow, being in the chair The meeting confirmed the appointment of the secretaries and treasurers who had previously been provisionally appointed An executive committee was appointed consisting of the presidents of the three medical corporations the three secretaries of the Scottish Committee—viz, Dr R Cranston Low, Dr J Walker Downie and Mr J Rutherford Hill—and Mr J L Ewing LL D

Dr J Adams intimated that the British Medical Association was willing and eager to do all in its power to aid the Fund, and it was agreed that the

DUBLIN CASTLE RED CROSS HOSPITAL SURGICAL DRESSERS —The honorary secretary of the Students' Union of the Royal College of Surgeons in Ireland was informed last week by Mr Seton Pringle, honorary secretary of the medical committee of the Dublin Red Cross Hospital, that the members of the Medical Units of all Officers Training Corps in Dublin have been recognised as official surgical dressers to that hospital There was an official opening of the hospital on Wednesday afternoon last, when the medical units paraded in the Upper Castle Yard

ADDITIONAL BOMBAY WAR HOSPITAL —The committee of the Bombay Presidency Branch of the Imperial Indian War Relief Fund have offered to the military authorities, through His Excellency the Viceroy, to provide a 500 bed hospital for Indian troops engaged in the war This offer has been accepted, and measures are now in progress for the organisation of this hospital which under the title of 'The Bombay Presidency Hospital" will be equipped, staffed, and maintained from the Bombay Presidency, including Sind, and will be located probably at some convenient base in Egypt or at any place that the military authorities may, with a view to the requirements of the British Indian Forces operating in the field, determine to be most desirable The expenditure incurred on the hospital will be entirely defrayed from the Bombay Presidency Branch of the Imperial Indian Relief Fund, in collaboration with the Women s Branch, and its general administration will be under the control of a special subcommittee appointed by the Administrative Committee of the Fund The Indian Council of the St John Ambulance Association, Bombay Presidency Centre, will also coöperate in the undertaking

RED CROSS GIFTS FROM INDIA —A return of the units received at the St John Ambulance War Gifts Depot, Bombay, up to Jan 5th shows a total of material representing a cash value of no less than 2¼ lakhs of rupees, or £15,000, collected in three months H H the Maharaja Scindia of Gwalior, in addition to the many generous contributions which he has already made towards the comfort and relief of the troops who are now fighting, has recently prepared and despatched to Bombay 500 units for the Indian Branch of the St John Ambulance Association Each unit makes provision of clothing and comforts for 10 wounded men

NAVAL WOUNDED FROM THE NORTH SEA —Our Edinburgh correspondent writes 'Last night, Jan 25th a ship of war landed at South Queensferry a number of men wounded in the North Sea battle on Sunday The cases numbered 26 and it is understood that none are of a grave nature The men were conveyed in motor ambulances to the Royal Naval Hospital South Queensferry For the second time since the war began Edinburgh Castle has been used as a hospital for German wounded sailors On Jan 25th 25 wounded sailors from the *Bluecher* were received at the Castle Hospital As soon as they arrived at the hospital every attention was shown to them by the medical officers in charge Fourteen of the men were badly injured and the officials of the Red Cross Society who have been engaged in dealing with wounded soldiers on their arrival in the city during the past few months say they are the most serious cases they have yet seen A number of operations were performed without delay One or two sailors are said to be in a precarious condition '

POSITION OF SAILORS AND SOLDIERS UNDER THE INSURANCE ACT —To the Medical Benefit Subcommittee of the Insurance Committee for the burgh of Edinburgh there has been submitted a memorandum issued by the Scottish Insurance Commissioners as to medical treatment of insured persons called up for service with His Majesty's Forces The memorandum states generally that insured persons who belong to the Naval or Army Reserve or to the Territorial Forces or have enlisted in the New Army are regarded as serving as sailors or soldiers from the moment at which they are called up or enlisted and accepted for service until the date of discharge During this period they are not entitled to medical or sanatorium benefits under the National Insurance Acts and accordingly no liability for their treatment [illegible] in the period [illegible] whom they have been [illegible] The position of such persons [illegible] by the [illegible] permitted temporarily to continue to reside at home, even though they may be concurrently engaged in civil employment An insured person who has been sent home owing to illness or in consequence of having been wounded must also be regarded as a serving sailor or soldier until the date of his discharge. Upon discharge, or in a case of a member of the Reserve or Territorial Forces, upon the demobilisation or disembodiment of these forces the insured person will again become entitled to medical benefit under the National Insurance Acts (unless otherwise disentitled)

Medical News.

UNIVERSITY OF OXFORD —On Jan 26th Convocation granted a decree to accept the sum of £450 offered by friends of the late Dr Francis Gotch F R S, Waynflete professor of physiology, to perpetuate his memory and to encourage physiological studies within the University It is proposed to establish a Gotch Memorial Fund the income to be expended upon an annual Gotch Memorial Prize, consisting of a bronze medal and a sum of £5 which will be awarded after examination to a member of the University who has worked in the University physiological laboratories for not less than four terms The remainder of the income will be applied to the establishment and maintenance of a Gotch Memorial Library in the University physiological laboratory —The following medical degrees were conferred on Jan 21st —

B M B Ch—C H L. Harper Wadham

UNIVERSITY OF CAMBRIDGE —The following medical degrees have been conferred —

M B B C—C C Kerby Trinity

SOCIETY OF APOTHECARIES OF LONDON —At examinations held recently the following candidates were successful in the subjects indicated —

Surgery —N W Rawlings (Section I) Manchester and E M Townsend (Sections I and II) Middlesex Hospital

Medicine —J A. W Robinson (Section I) King s College Hospital and M C Stark (Section I) London Hospital

Forensic Medicine—C D Banes W F Matthews and J A. W Robinson King s College Hospital and M C Stark London Hospital

Midwifery —C D Banes King s College Hospital H A. de Morgan Middlesex Hospital W F Matthews King s College Hospital D C Ogilvie Middlesex Hospital J A W Robinson, King's College Hospital and M C Stark London Hospital.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW —The quarterly examinations of the above Board held in Edinburgh, were concluded recently with the following results —

FIRST EXAMINATION

Chombil Vittil Appunni Menon and Kalkhasru Sorabji Bhiwandiwalla.

Physics —Rebecca Goodman Gordon Spivey Woodhead, William Bethune Stott and John Lawson Gibson

Biology —Gwilym ap Vychan Jones and Joseph Raymond Welply

Chemistry —Frederic Leo Jones and Muriel Keyes.

SECOND EXAMINATION

Shapoor Dinshaw Vania, Robert Gloag Battersby Lawson Lamb Steele Thomas Jackson Thomas Robert Wilson Alfred Black, Don Adrian Jayasingha, and Arukatti Patabendige Frederick Abeysuriya.

Anatomy —Oswald Johnston and Buenaventure Ramirez

Physiology —Harold Gengoult Smith and Janie Isabel McBirnie

THIRD EXAMINATION

Charles Harris Henry Valentine Fitzgerald Robert McGregor William McAlpine Andrew Matheson Edward Spence and John Alexander Smith

Pathology —Frederick Charles Joseph Mitchell and Iwan Davies

Materia Medica—James Stewart Durward Owen Glendower Evans Frederick Joseph Jack Harry [illegible] Norman Stewart Bruce John Joseph Mulsey and Paul [illegible]

FINAL EXAMINATION

THE APPEAL FOR SURGICAL INSTRUMENTS

The Master of the Society of Apothecaries acknowledges with thanks the receipt of surgical instruments kindly contributed by the following donors since the publication of the last list —

Mr Brown, per the Weybridge Cottage Hospital, Dr W A. B Young, Blackburn, Mr F Lett Hastings, Dr B Lewis Paton, Rugeley, Staffs, Mrs K E Raston, Ashford, Barnstaple, Doctors resident in the Barnsley area of the B M A, per Dr R F Castle, Darfield

The War.

THE BRITISH RED CROSS SOCIETY —The summary of the work for the week ending Jan 23rd states that since the last report there have been despatched to Calais 4 lorries to Boulogne 2 motor cycles, 1 lorry, and 1 soup kitchen, and 4 ambulances to various places in England

The number of auxiliary home hospitals accepted by the War Office is now 705 containing beds for 19 576, including 417 beds accepted during the past week. In Netley Hospital there are now 180 British, 194 Indians and 6 Belgians Arrangements are being made to accommodate the Japanese Red Cross surgeons and nurses in two of the hospital huts The Lord Iveagh "Irish Hospital" extension is progressing

During the week the expeditions to Serbia and Montenegro were despatched under the supervision respectively of Mr James Berry and Dr F G Clemow Sir Thomas Lipton s generosity in regard to these units has been very great

The total number of cases of stores sent abroad last week was 467, of which 232 were despatched to Boulogne, 113 to Calais, and 50 to Dunkirk 104 hospitals at home were supplied with 721 cases of stores The ambulance ships were provided as usual with their weekly supply of garments and comforts for the wounded 11 052 garments were received during the past week and 14 036 were issued. Of these, 10,331 were sent to hospitals in this country

SECOND LONDON (CITY OF LONDON) GENERAL HOSPITAL —More than four months ago we described briefly in this column the manner in which St Mark s College Chelsea and its adjacent buildings were being converted into a complete military general hospital of 520 beds under the skilful supervision of Lieutenant-Colonel E M Callender the commandant. The work of adaptation was begun on August 10th, and the buildings were open for the reception of patients on Sept 7th while the first patients were admitted five days later The number of beds belonging to this hospital is now nearly 900, for in addition to the 520 at St Mark s College there are sections at St Thomas s Hospital (233 beds) Victoria Hospital for Children (40 beds), Great Northern Central Hospital (65 beds), and the Richmond Red Cross Hospital (40 beds) Up to the close of last week 4323 patients had been admitted, including 140 officers, and the number of deaths was less than 20 The vast majority of the cases treated have recovered and gone back to military service A brief inspection of the whole institution in company with the commandant made it evident that the great organisation which came into being only a very few months ago has settled down into working order, and that all the wheels are moving with the utmost smoothness The cheerfulness of all the inmates was very noticeable

More than 500 operations have been performed in the theatre, but these have included few amputations Very few cases of undoubted tetanus have reached this hospital from the front Of the four patients two recovered and two died All cases with septic wounds have injections of tetanus antitoxin as a precautionary measure, and the septic wounds, of which there have been a great many have done extremely well as a whole Among the remarkable cases which have been under treatment the following three may be briefly mentioned here 1 A bullet entered the abdomen half an inch above the pubes in the mid line The wound of exit was just at the side of and below the tip of the coccyx. There were no symptoms at all from first to last, and the only sign was that after 14 days the patient had a seminal emission consisting largely of blood 2. A bullet entered the side of the head just below the level of the lower end of the mastoid process It came out at a similar place on the opposite side Although for a time there was great muscular stiffness and vertigo on walking, the patient made a complete recovery 3 A rifle bullet entered the back of the leg just about the popliteal space It passed downwards and forwards and went right through the knee joint, passing through the intercondylar notch It was found in the ligamentum mucosum and removed. The strange feature was that no important tendon, nerve or vessel was injured, and there was no fracture of any bone

Largely through the instrumentality of Mr C Arthur Pearson it has been decided by the War Office that all cases rendered totally blind in consequence of wounds shall in future be drafted to this hospital where arrangements have been made for them to be visited at the earliest moment by representatives of Mr Pearson's organisation, so that education may be begun without delay and some of the mental misery lifted from them by personal contact with blind instructors Afterwards when they are invalided out of the service these blind soldiers will be drafted to a convalescent home for the blind Among the surgeons on the *à la suite* staff of the hospital four—Sir Arbuthnot Lane, Sir Frederic Eve, Mr G H Makins, and Mr E H Fenwick—have left to take up other duties in connexion with the war whilst another surgeon has dropped out through ill health Thus only one of the surgical staff has not been called up so far for active duty at the hospital.

Sir Ronald Ross, K C B, F R S, has been appointed consulting physician in tropical diseases to the Indian troops in Europe

Surgeon-General W D C Williams, C B commanding the medical units of the Australian Imperial Force in Egypt had the honour of being received by the King at Buckingham Palace on Monday last

SOLDIERS AT ST THOMAS S HOSPITAL —At the last court of governors the treasurer Mr J G Wainwright reported that since the opening of the military wards 911 soldiers from the front including 100 officers had been treated at St. Thomas s Hospital, the hospital bearing all expenses

Dr Edmond Lagelouze docteur en médecine de la Faculté de Paris of Bethisy S Pierre Oise together with three other inhabitants of the same commune has by special desire of the King been enrolled an Honorary Associate of the Order of the Hospital of St John of Jerusalem in England in recognition of distinguished services and great humanity to a wounded British officer on Sep 1st

CANCER HOSPITAL, Fulham road, S W —House Surgeon for six months Salary £100 per annum

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR, and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice

It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession may be sent direct to this office

Lectures original articles and reports should be written on one side of the paper only AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters whether intended for insertion or for private information must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor"

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index and Title-page to Vol. II of 1914 were given in THE LANCET of Dec 26th 1914

VOLUMES AND CASES

VOLUMES for the second half of the year 1914 are now ready Bound in cloth, gilt lettered, price 16*s*, carriage extra.

Cases for binding the half year's numbers are also ready Cloth, gilt lettered, price 2*s*, by post 2*s* 3*d*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months ..	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs 50 per month)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

TO COLONIAL AND FOREIGN SUBSCRIBERS

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS WILLIAM WOOD AND CO, 51, Fifth Avenue New York, U S A

Notes, Short Comments, and Answers to Correspondents.

POPULAR MEDICINE IN GERMANY

MODERN *Germany is greatly victimised by quacks* and any one who has had to do with a *hoch kultivirt* German or Austrian knows how *much* he *or* she is likely to be the dupe of dietetic and therapeutic *faddists* The attitude adopted is one of quaint, solemn, and almost grotesque caution in matters of domestic medication Such a work, for instance, as Father Kneipp's "My Water Cure," which attained its jubilee in 1896, may be compared to John Wesley's "*Primitive Physick*," of which the twenty first *edition* appeared in London in 1785 while the last and *twenty seventh edition* was published in New York in 1814 Father Kneipp, *who* was Secret Chamberlain to the Pope and parish priest of Wörishofen, in Bavaria, made a grand discovery when, about 50 or more years after the English, he found out the virtues of cold water Throughout *his book* he regards cold water with solemnity as though it were a scarce and valuable but rather dangerous drug He fights the good fight in its cause, and *demolishes* the objections of those who object to it on the grounds *of* 'extraction of warmth" His illustrative anecdotes are delightful—a *picture of* domestic Germany throughout the nineteenth century We read for instance, of the "gentleman of high position who had an excessive aversion for water," and whose neck was so sensitive that he scarcely knew how to take enough care of it" The picture of Father Kneipp himself seated in a cold bath in midwinter and sponging the lower half of his stomach is meant *to excite respect for his courage* as an innovator The record of *the* "Masserl' *or* highest number of pints, sometimes amounting to 10, which could be taken by the *winner in* a water-drinking tournament, is given as proof of self devotion to a new cause

THE OWNERSHIP OF BULLETS

To the Editor of THE LANCET

SIR,—With reference to the amusing and interesting remarks *of a* Swiss *correspondent in* THE LANCET of *Jan* 23rd *referring* to the ownership of bullets, I have some recollection of an action at law in one of the continental courts being reported in your columns, where a young man claimed the bullet as he wished to have it mounted in gold as a trinket This idea of the souvenir seems to be mainly at the bottom of the question, and is one which also concerns the jeweller perhaps I read not many weeks ago that a German or Austrian lady of high rank was having certain soldiers' bullets mounted in gold for them free of charge The question as to ownership has its comic side, and you reported once in THE LANCET the case of a bullet being extracted from a marine after it had worked its way from the hip to the calf, after being 42 years in the man's body

I am, Sir, yours faithfully,

ALBUS

Jan 25th, 1915

TREATMENT OF THREADWORMS

F F, a medical man, asks if any practitioner can suggest treatment for a case of threadworms of long duration in an adult The patient has had treatment in the country and also from London consultants without permanent benefit, and our *correspondent is at a loss* what further to do

BOVRIL PICTURES

Messrs Bovril, Limited have forwarded us copies of the three bonus pictures of their current picture scheme, the largest being framed and the other two unframed The large picture is an artist's proof of a photogravure after a painting by Mr Arthur Elsley, entitled "A Private Rehearsal" and depicts a little girl performing a pirouette *sur la pointe du pied* in a drawing room to the delight of the assembled company of young and old Another work by the same artist is entitled Good Night," and represents a young mother about to put the last born in its cot in the presence of its brother and sister The third picture is by Mr A de Breanski jun, is entitled 'A Welsh Valley, and shows a mountainous background and a rushing stream with stepping stones being crossed by a peasant The atmosphere is well managed The pictures have all been produced by Messrs C W Faulkner and Co, of London in their usual excellent style

Messrs John Bell and Croyden Limited of 50 Wigmore street London W have published a card which contains a monthly calendar and a brief summary of the most important changes in the new *British Pharmacopœia* A copy will be sent to any of our readers on application

Mr Cuthbert Reid —We fear we could not reprint the article but some further reference to the subject might be made

Remarks
ON
PUERPERAL ECLAMPSIA

Being the Introduction to a Discussion at the Midland Medical Society on Jan 27th 1915,

BY C E PURSLOW M D LOND,
M R C P LOND
HONORARY OBSTETRIC OFFICER, QUEEN'S HOSPITAL, BIRMINGHAM
LECTURER ON MIDWIFERY AND DISEASES OF WOMEN UNIVERSITY OF BIRMINGHAM CONSULTING SURGEON
BIRMINGHAM MATERNITY HOSPITAL AND
LYING IN CHARITY

MR. PRESIDENT, LADIES, AND GENTLEMEN,—For the purposes of this discussion I will divide the subject into the following sections I, Prophylactic Treatment, II, Treatment of the Fits and of the Toxæmia III, Obstetrical Treatment

I —PROPHYLACTIC TREATMENT

As regards prophylactic treatment there can be no doubt that in many cases in which the disease is threatened it can be warded off by appropriate means, and success depends on an early recognition of symptoms of the pre eclamptic state, these are numerous, but I should say that the most constant and important are albuminuria, persistent headache and œdema Other symptoms may be disturbances of vision and hearing and vomiting One prodromal symptom which is not common, but which when it occurs is, in my opinion of most unfavourable prognostic import, is severe epigastric pain The albuminuria associated with eclampsia in which there is usually a large amount of albumin present, is practically confined to the later half of pregnancy, cases of eclampsia before then being rare Pronounced albuminuria in the later months is a dangerous complication for both mother and child, and the danger of the condition is greatly increased by the fact that it is so often unrecognised and untreated until the sudden onset of a convulsion calls attention to the case

It should be made a rule to examine the urine of every pregnant woman in the latter half of pregnancy, and the examination should be repeated at intervals, shorter as full term approaches, if this rule were adhered to the death rate from eclampsia would be greatly reduced It should always be borne in mind that a haze of albumin may be due to mixture with vaginal discharge, so that if albumin is present in the specimen passed by a patient we should never base a diagnosis or treatment on that, but should examine a catheter specimen If on the other hand, there is no albumin in the specimen voided by the patient it will not be necessary to pass a catheter If albumin is present a microscopical examination and an estimation of urea are advisable Statistics show that this disease is more likely to occur in primiparæ and in my experience it has seemed that its occurrence was more to be feared in well developed women who had been in the habit of taking a large amount of exercise and eating much solid food

When albumin is found in considerable quantity in the urine of women in the later months the case should be taken in hand at once In the first place the patient should be confined strictly to bed and it is a very good plan to commence the treatment by giving nothing else but hot water for the first [illegible] hours Afterwards milk well diluted may be given and the diet should be limited to this until there is distinct improvement in the secretory action of the kidneys Free purgation is essential and for this purpose 30 gr of pulv jalapæ may be given, or sodii sulph ʒi, in water ℥ii., every two hours, until free purgation is produced Rectal injections of normal saline may be given after the bowels have been well emptied, or saline may be given sub cute If in spite of this treatment the renal secretion does not improve or if prodromata of eclampsia come on, the difficult question of induction of premature labour presents itself. On the whole, I am inclined to advise that labour should not be induced I have seen some most satisfactory cases in which the treatment already set out has been followed by spontaneous delivery without the occurrence of eclampsia, even when the patient has seemed to be on the verge of an attack

II —TREATMENT OF THE FITS AND OF THE TOXÆMIA

The practitioner is generally sent for as soon as a fit has occurred, and in some cases it will happen that there will have been no prophylactic treatment because the patient had not been under medical care, and neither she nor her friends will have suspected that anything was wrong until they are alarmed by the occurrence of a fit The patient should be at once put to bed in a darkened room and preserved from all external causes of irritation as far as possible An efficient nurse should be obtained, and she should be instructed that if another fit comes on the patient should be watched carefully to see that no harm befall her, as by suffocating in the bedclothes or falling out of bed During the fit a piece of wood should be placed between the teeth to prevent the tongue being badly bitten It is a good plan to place one side of the bed against the wall, as the nurse can then more easily control the patient During the coma which follows a fit the head should be brought to the edge of the bed and turned well over on one side so as to allow saliva to escape and prevent it entering the trachea

I may say here I am sure that those who have had cases of this kind among the poor will have appreciated the advantages of obtaining admission for them to the Maternity Hospital, which, if only for the treatment of this disease has proved a most valuable addition to the charitable institutions of the city If the patient is able to swallow she may be given water but no food, not even milk, should be given A quickly acting aperient may be given, and one of the best is croton oil ♏ ii, made up with powdered sugar and placed on the tongue, in addition a copious enema of soap and water may be given, and when this has acted a further rectal injection may be slowly given of 4 ounces of water containing 2 ounces of sulphate of magnesia If the apparatus is at hand it is also well to wash out the stomach Poultices to the loin probably encourage action of the kidneys and at all events can do no harm I am not in favour of hot air baths One of the few methods in addition to purgation upon which almost all writers are agreed is the administration of subcutaneous or intravenous injections of saline chloride of sodium ʒi to the pint, or better still ʒi each of chloride and acetate of sodium the salt may be obtained ready for use in glass containers, and Horrocks's small saline infusion apparatus is in my opinion the best and simplest and should be carried in every midwifery bag

Before proceeding to discuss the obstetrical aspect of the question I will refer briefly to some of the numerous other methods which have been advocated for dealing with the fits and toxæmia

EXPERIMENTAL PURPURA

(Second Communication)

BY J C G LEDINGHAM M B, D Sc ABERD,
CHIEF BACTERIOLOGIST LISTER INSTITUTE
AND
S. P BEDSON M D, M Sc DURH
LATE BRITISH MEDICAL ASSOCIATION RESEARCH SCHOLAR,
LISTER INSTITUTE.

IN a preliminary communication by one of us (Ledingham[1]) to this journal on June 13th 1914, the production of purpura hæmorrhagica in guinea pigs, after inoculation with an antiserum prepared by immunising rabbits with guinea pig blood plates, was placed on record The present paper deals mainly with conjoint work carried out in June and July of last year, together with additional experimental data since obtained by one of us (L) in the absence of the other (B) on military service The blood changes in guinea pigs inoculated with anti-plate serum have been followed out in detail, and we propose in the first place to submit data on this point A description will follow of experimental purpura in the rabbit and rat induced by inoculation with their respective anti plate sera.

Blood Changes in Guinea pigs after Inoculation with Anti guinea pig plate Serum

Notes on technique—The blood plates were counted in a Thoma-Zeiss chamber, the blood from the ear being received into citrate solution containing brilliant cresyl blue which showed up the blood plates very clearly The figures for the plate content per c mm obtained by this method in a series of normal guinea pigs were as follows 856 000, 752 000 340 000 640,000 672,000, 683 000, 590,000, 696,000 664 000, 592,000 (the latter four obtained from the same animal on four successive days), 592,000, and 584,000 The average of nine animals works out about 638 000 per c mm The hæmoglobin was estimated by Haldane's instrument Attempts were also made to obtain coagulation times, but as we have not satisfied ourselves that the methods employed yield reliable results, at least so far as the guinea pig is concerned, we refrain at present from alluding to them The statement in the preliminary communication that the clotting is delayed rested entirely on observations of the bleeding time after puncture Prolongation of the bleeding time after puncture of the ear vein is a very marked feature in experimental guinea pig purpura (as Duke asserts to be the case in human purpura), but this function may prove to have no direct relation to the coagulation time as ordinarily understood and calculated

The three animals B 3, B 4 and B 5 whose blood changes &c have been followed daily, received each one dose of anti plate serum (1 5 c c) subcutaneously immediately after the control normal samples had been taken The animals were purposely chosen of large size (over 400 gm), so that a lengthy observation period would be available before the fatal conclusion (or possibly recovery) resulted It had previously been determined that in animals of 250 grm a dose of 1 c.c of a particular batch of anti plate serum had produced death in three, four or five days with typical purpuric lesions The data obtained from these three [illegible] animals together with notes of the general condition are found in Table I (see p 312)

Remarks on Table I—It will be observed from the table that two of the animals died in 4 and 8 days respectively, while the third animal (B 3), whose initial weight was 450 gm., made a complete recovery after exhibition of purpuric skin lesions On July 14th—i.e, 36 days after the first dose—it received a second dose of 2 c c of the serum The reaction to this second dose was very slight, the blood plates only, showing a marked fall, while the purpuric skin spots were few It is impossible here to analyse the blood changes in detail, but certain points deserve notice 1. The total leucocyte count is not appreciably affected, though there is a distinct tendency to relative lymphocytosis (see the column of differential counts) 2 The blood plates are the elements which suffer the earliest and promptest reduction. Except in the case of B 5 which showed an abnormally low initial plate content, the plates fell to one sixth to one tenth of their initial figure In animal B 3, which recovered, the rapid regeneration of red cells and hæmoglobin is well seen. In the last two columns data are appended with reference to the presence of hæm agglutination in the shed blood, the minute changes in the red cells, and the general condition of the animals

Post-mortem appearances of the above three animals *B 3*—Killed for examination on July 18th A few skin hæmorrhages present at site of last inoculation. A few groups of faded punctiform hæmorrhages in stomach wall No petechiæ on heart or lungs Lymph glands not of hæmolymph character Urine not stained with hæmoglobin.

B 4.—Dead June 16th This animal had shown numerous skin hæmorrhages during the early days following inoculation of the serum At necropsy these had faded and skin hæmorrhages were found only in the neighbourhood of the inoculation site The red colour of the lymph glands was disappearing Several hæmorrhages in the lungs and very numerous petechiæ in intestine Stomach mucosa showed two round patches—one about the size of a sixpence the other half that size—studded with small punctiform hæmorrhages There was no ulceration. Liver yellowish. Spleen large, dark red, and friable Kidneys and adrenals apparently normal

B 5—Dead June 12th Numerous hæmorrhages at site of inoculation and a few scattered about elsewhere Only a few lymph glands show the hæmolymph change No hæmorrhages in intestine Liver pale and yellowish Spleen greatly enlarged and friable. Urine blood stained A few small hæmorrhages in testicles *Both eyes show cataract*

Blood Changes in Smaller Animals

To complete this part of the subject tables are also appended showing the variations in the red cells, blood plates, hæmoglobin, &c., in three guinea pigs of less weight Each was inoculated on June 30th, 1914 with 1 c c of anti plate serum subcutaneously (See Tables II A, II B, and II C)

TABLE II.A.—*Guinea pig 8*

Date		Red cells		Plates		Hb		Weight
June 30th*	—	[illegible]	—	[illegible]	—	[illegible]	—	[illegible] gm
July 1st	—	[illegible]	—	512,000	—	[illegible]	—	220 ,,

Death between 1 and 2 P M on July 3rd

* Received 1 c c anti plate serum subcutaneously

Notes on blood picture and general condition—July 1st Blood picture normal except for one or two red cells showing polychromatophilia Well marked hæmagglutination. Pig lively Diffuse infiltrate over abdomen July 2nd Some irregularity in shape of red cells Megalocytes of medium size fairly numerous mostly show polychromatophilia. Some red cell shadows Pig seems ill Infiltrate softening Some skin hæmorrhages Gums of fairly good colour July 3rd Hæmagglutination of shed blood more pronounced Great irregularity in size of red cells Megalocytes showing and I hope that we may hear their virtues or faults described in the discussion

---

[1] [illegible] THE LANCET, [illegible]

Chloroform—If any operative interference is contemplated, even such a small procedure as puncture of the membranes, chloroform should be given, but I am entirely opposed to the method so frequently adopted of attempting to control the convulsions by its continuous or intermittent administration

Morphia—This treatment has been extensively advocated of late years, it is given by hypodermic injection in an initial dose of ½ grain and subsequent doses of ¼ grain until a total amount of 2 grains has been reached I have tried it, but have not been convinced of its advantages, and have not used it lately, and I would say the same of *venesection*

Thyroid extract in doses of 30 to 40 grains has been suggested by Nicholson, of Edinburgh, who reports good results from its use

Nitro glycerine in subcutaneous injection up to 5 minims has been tried with successful results by Dr McCarthy, one of our past presidents, and I have no doubt some of those present may be able to speak of its use

Veratrum viride has been extensively used in America, and recently Haultain, of Edinburgh, has brought forward several successful results from the hypodermic injection of veratrone This remedy is said to be particularly indicated in cases of high pulse tension

Pilocarpine has been extensively used, but on account of its tendency to increase bronchial secretion it is, in my opinion, a dangerous drug

Oxygen inhalation in cases where cyanosis is a marked symptom would be highly desirable

Cold baths are said to be useful in cases in which hyperpyrexia is a marked symptom, this is a not infrequent complication of eclampsia, and is one of bad prognostic import

Decapsulation of the kidneys and *lumbar puncture* have both been advocated and practised, but only to a limited extent, and apparently without any striking success

III—OBSTETRICAL TREATMENT

There have been many differences of opinion revealed in the methods of treatment we have already been considering, but when we enter on the consideration of the obstetrical treatment we might describe the authorities as being divided into two hostile camps, their actions depending in a large degree on the views they hold as to the causation of eclampsia The one, which I may call the Rotunda school, believes that the toxin is elaborated from the food taken in by the mother owing to some faults in her metabolism The other, or what I may call the German school, considers it to be due to the fœtus, and has advanced the theory recently that the symptoms are due to placental albumin finding its way into the maternal blood stream in quantities greater than can be dealt with at the time by the antibodies which are elaborated to deal with it It is on the presence of these antibodies in the maternal blood that Abderhalden's serum test for the diagnosis of pregnancy is based Those holding the first view advise little or no interference with the process of labour, while to those holding the second no methods are too radical—~~induction of labour~~, accouchement forcé, vaginal and abdominal Cæsarean section being each advised in particular cases

Personally, if labour has started and can be terminated quickly under an anæsthetic by forceps I should not hesitate to interfere, but the difficult cases are those in which severe eclampsia is in progress, fit succeeding fit, with no lucid interval and in which there is no sign of labour, the os remaining closed and the cervix not taken up

I have treated cases of this kind on both the expectant plan and on the lines of active interference In an article on the treatment of eclampsia which I wrote three years ago for Latham and English's "System of Treatment" I stated that, on the whole, I thought that the results from interference were slightly better than those obtained when no steps were taken to evacuate the uterus, since then, as a result of further experience of the policy of non interference, I am inclined to modify those views, and the results in the last case which was under my care were so striking that I may *perhaps be pardoned for quoting it*

The patient was admitted to the Queen's Hospital, Birmingham on Dec 1st last on the recommendation of Mr Sydney E Price, of Dudley Port She was a primipara, 23 years of age well developed, and in the seventh month of pregnancy, she had been having fits for about 48 hours and had had more than 80 altogether

On admission the patient was œdematous, comatose, and her heart beat was 160 and the pulse uncountable at the wrist She was given an enema and subsequently a *rectal injection of ℥ii magnes sulph in water* Two pints of saline were then injected slowly into the submammary region She was admitted at 1 A M No obstetrical treatment was adopted and at 7 30 A M she delivered herself of a stillborn male child by the breech, the placenta did not *come away and had to be removed* by hand During the day she had another subcutaneous saline and mag sulph injection by rectum every six hours She remained completely comatose for 36 hours, then slowly recovered consciousness and began to pass urine and left the hospital well on the ninth day after admission

This case was a striking illustration of the success of this line of treatment, which was carried out entirely by Miss Hemingway, my house surgeon, to whose persevering and careful attention the patient largely owes her life If we decide on an active line we have a large number of measures open to us, and I will briefly consider these They are puncture of membranes, bougies, packing the cervix and vagina, tents rubber dilating bags, digital dilatation or dilatation by Bossi's dilators, followed by version or forceps, deep incision of the cervix, including the so called vaginal Cæsarean section, and abdominal Cæsarean section

Puncture of the membranes can be done with little disturbance of the patient, and is a harmless proceeding, it rapidly diminishes intrauterine tension, but as a means of inducing labour it is very uncertain in the time it takes, if done, every antiseptic precaution should be taken

As regards the other *methods, I would say* emphatically of the slow *ones* (under which I include bougies, tents, packing of the cervix and vagina, and rubber dilating bags, including that of Champetier de Ribes) that they are contraindicated in the treatment of eclampsia and if there is one thing about which I am convinced in this question it is that *interference*, if *decided upon* should be by rapid methods under anæsthesia and I would select dilatation by Bossi's dilator or vaginal or abdominal Cæsarean section I think that, on the whole for this class of case the form of active treatment likely to be least prejudicial would be abdominal Cæsarean section but I feel convinced that if a *good trial* be given to the milder methods it will be found that the results will be better than those obtained by the most heroic operative procedures polychromatophilia, very numerous poikilocytes, no punctate basophilia. A few normoblasts, some showing pyknosis and karyorrhexis of nucleus. A few red cells with "Jolly" bodies. Pig cold and collapsed, blood thin and watery; no eye changes observed. Post mortem: Gelatinous blood-stained infiltrate over abdomen and thorax. A fair number of small punctiform hæmorrhages in skin. Numerous hæmorrhages in subcutaneous tissue. No eye changes. Spleen dark red and friable. Bladder filled with dark, blood-stained urine. Testicles showed several large hæmorrhages. No hæmorrhages in stomach or intestines. Lymph glands of red hæmolymph character. Bone marrow dark red.

TABLE II.B.—*Guinea-pig 9.*

Date.	Red cells	Plates	Hb	Weight

July 1st	5,952,000	480,000	96%	260
2nd	5,616,000	272,000	84%	240 ,,
3rd	720,000	392,000	16%	230 ,,

Death between 1 and 2 P.M. on July 3rd.

* At 5 P.M. received 1 c.c. anti-plate serum subcutaneously.

Notes on blood picture and general condition.—July 1st: Pig lively. Well-marked firm infiltrate over abdomen and extending forward to thorax. Blood picture normal except for one or two red cells showing polychromatophilia. July 2nd: Hæmagglutination well marked. Some red cell shadows. Irregularity in size of red cells commencing. Megalocytes of medium size showing polychromatophilia but not numerous. Animal ill. Infiltrate softening, some skin hæmorrhages, gums of good colour. July 3rd: Hæmagglutination extreme. Blood very watery, oozing after vein puncture. Irregularity in size of red cells. Megalocytes showing polychromatophilia, a few deeply basophile red cells, some poikilocytes. A few normoblasts, some showing punctate basophilia of cytoplasm. Pig collapsed and cold. No eye changes visible. Post mortem: A few small punctiform hæmorrhages in skin. Glands do not show hæmolymph change. No eye changes. Bladder contained dark blood-stained urine. No hæmorrhages in internal organs.

TABLE II.C.—*Guinea-pig 10.*

Date.	Red cells.	Plates.	Hb	Weight
June 30th*	6,6[illegible]0,000	6[illegible]3,000	102%	360 gm.
July 1st	6,170,000	334,000	100%	320
2nd	5,501,000	[illegible]20,000	84%	300

Death during night of July 2nd-3rd.

* At 5 P.M. received 1 c.c. anti-plate serum subcutaneously.

Notes on blood picture and general condition.—July 1st: Blood picture normal. Hæmagglutination well marked. Pig lively. Infiltrate not very well marked. July 2nd: Irregularity in size of red cells. Fair number of megalocytes mostly showing polychromatophilia. Some red cell shadows. Pig not well. Infiltrate more marked but softer. Some skin hæmorrhages, one about the size of a threepenny piece. Post mortem: Well-marked gelatinous blood-stained infiltrate. Numerous small punctiform hæmorrhages in skin. Glands of hæmolymph character. A few small hæmorrhages in lungs and in wall of left ventricle. Spleen much enlarged and friable. One or two minute petechiæ in pancreas. Bladder full of blood-stained urine. Numerous hæmorrhages in wall of large gut and in testicles.

Remarks on Tables II A, II B *and* II C.—These three animals, whose initial weights were 240 gm., 260 gm., and 360 gm., did not survive beyond the third day. All showed pronounced purpura. The effect of the serum on the blood elements is essentially similar to that obtained in the case of the larger animals of Table I. Notes regarding the minute changes in the red cells, the general condition of the animals during life, and the post-mortem appearances are appended to the tables.

Control Experiments with other Sera. Action of Anti-leucocytic Serum.

This serum was prepared by immunising rabbits with leucocytes obtained from the peritoneal exudates of guinea-pigs which were killed [illegible] hours after an intraperitoneal inoculation of 5-10 c.c. of sterile broth. Such exudates, as is well known, consist almost entirely of polymorphonuclear leucocytes, and if great care is taken in manipulation of the animals after death the risk of admixture with red cells can be very largely avoided. The exudates are taken up in citrated saline and thereafter washed in normal saline. The serum of the rabbits so immunised proved to be quite as fatal to guinea-pigs as the anti-plate serum, but did not produce purpuric phenomena. We append two tables (Nos. III.A and III.B) showing the action of the serum on the blood elements throughout the course of the experimentally induced disease.

Death at 3 P.M. on July 11th.

* At 5.30 P.M. received 1 c.c. anti-leucocyte serum subcutaneously.
† P = Polymorphonuclears. E = Eosinophiles. L = Lymphocytes. Ma = Mast cells.

Blood picture and general condition.—July 9th: Red cells irregular in size, numerous polychromatophilic megalocytes, a few red cells showing "Jolly" bodies, no nucleated red cells. The polymorphonuclear leucocytes are degenerated, their protoplasm being vacuolated and the granules appearing as indistinct basophile knots in cytoplasm. Pig ill. Small infiltrate under skin, no skin hæmorrhages. July 10th: Large numbers of megalocytes, some microcytes, well-marked polychromatophilia, nucleated red cells (normoblasts) 1·5 per cent. of white cells. Some phagocytosis of red cells by mononuclears. General condition unchanged. No skin hæmorrhages. July 11th: Some red cells show punctate basophilia, nucleated red cells (normoblasts and megaloblasts) 21 per cent. of white cells. Neutrophile myelocytes present. Pig ill and collapsed, hæmoglobinuria, no eye changes. Post mortem: No skin hæmorrhages. Lymph glands appear normal. No hæmorrhages in internal organs. Spleen greatly enlarged and friable. Bladder full of blood-stained urine.

11th	1,6[illegible]5,000	[illegible]	13,200	3·0%	67·5%	0·5	22·0%	200

Pig dead at 6 P.M. on July 12th.

* At 5.30 P.M. received 1 c.c. anti-leucocyte serum subcutaneously.

Blood picture and general condition.—July 9th: Slight hæmagglutination. Irregularity in size of red cells, poikilocytes, polychromatophilic megalocytes, one nucleated red cell seen. Degeneration of polymorphonuclears as in No. 15. Pig seems ill. Very slight infiltrate, no skin hæmorrhages. July 10th: Marked irregularity in size of red cells, no nucleated red cells. Infiltrate soft, no skin hæmorrhages. July 11th: Many megalocytes showing polychromatophilia, some red cells with punctate basophilia, nucleated red cells (normoblasts) 3·5 per cent. of white cells. Phagocytosis of red cells observed. Myelocytes 4 per cent. (total neutrophiles, 3[illegible] per cent.). Pig very ill. No eye changes. Post mortem: No skin hæmorrhages. No eye changes. No hæmorrhages in internal organs. Spleen slightly enlarged. Hæmoglobinuria. Liver yellowish.

* Subcutaneous injection of 1·5 c.c anti-guinea pig platelet serum.

† Received second dose of 2 c.c.

Blood picture and general condition.—July 16th: Hæmagglutination present. Some irregularity in size of red cells, a few red cells showing polychromatophilia, one or two nucleated red cells seen. Rabbit quite lively. Bleeds very readily when ear vein is punctured, marked purpura over entire skin. July 17th: No nucleated red cells seen, a few showing polychromatophilia. Rabbit quite lively. No fresh outburst of purpura so far as can be detected. Post mortem: Extreme purpura of skin. Lymph glands not of frankly hæmolymph character. A few punctiform hæmorrhages in stomach and large gut. Some extensive hæmorrhages in muscles of thigh. No hæmoglobinuria.

* At 4.15 P.M. received 3 c.c. anti-rabbit plate serum intraperitoneally.

Blood picture and general condition.—July 20th: Before injection one or two nucleated red cells were seen in film. July 21st: Little change in red cells, one normoblast seen. Animal drowsy and unwell. Hæmorrhages in skin and specially marked in skin of ears. The flicking or rubbing of the ears produces an immediate crop of small punctiform hæmorrhages. July 22nd: Many red cells showing polychromatophilia, marked irregularity in size of red cells, no nucleated red cells seen. Rabbit quite lively. Hæmorrhages still present in skin. July 23rd: Marked irregularity in size of red cells, some large megalocytes showing polychromatophilia, no nucleated red cells seen. Animal's condition good. July 29th: Animal's condition good. Purpuric spots in skin mostly faded. A few still present on ears.

Killed with ether at 2 P.M. on July 23rd.

* At [illegible] P.M. received 3 c.c. anti-rabbit plate serum intraperitoneally.

Blood picture and general condition.—July 20th: Before injection no nucleated red cells were seen. July 21st: Hæmagglutination present but not marked. Some irregularity in size of red cells, some poikilocytes, no nucleated red cells. Animal ill. Hæmorrhages in skin, and especially in skin of ears. July 22nd: No nucleated red cells. Animal's condition unchanged. July 23rd: No nucleated red cells. Condition unchanged. Post mortem: Skin shows numerous hæmorrhages. Lymph glands appear normal. Numerous intramuscular hæmorrhages in diaphragm. No hæmorrhages in stomach or intestine, no hæmoglobinuria. Some hæmorrhages of moderate size in thigh muscles.

It will be seen that all three animals developed marked generalised purpura from which they recovered. They were, however, killed for examination purposes at various dates, and the post-mortem appearances are appended to the tables. The marked and early fall in the plate content corresponding with the early onset of purpuric skin phenomena will be noted. In these rabbits coagulation times were taken by the Dale-Laidlaw method,[3] the blood being drawn into short capillary tubes, each containing a small shot. The data so obtained are included, but we are not satisfied that they can be depended upon in view of the variations we have obtained by this method in normal rabbits examined at short intervals. This question is reserved for further investigation.

Experimental Purpura in the Rat.

Rabbits were immunised with rat platelets recovered from fairly large quantities of rat blood. Each immunising dose consisted of the plates obtained from the mixed blood of 24 sewer rats. Three rabbits were immunised, two of which died during the course of immunisation. From the remaining rabbit a small test bleeding was taken a few days after it received its second dose. The serum so obtained was tested on a rat and found to be efficacious in producing purpura (see below). The rabbit received a third and a fourth dose of rat plates, but unfortunately a few minutes after the intravenous injection of the latter dose it developed marked anaphylactic symptoms. It was felt that the serum of such an animal would probably be largely deprived of its anti-plate elements owing to absorption by the large dose of fresh plates injected. The animal was, however, bled when moribund and the serum so obtained filtered. As we shall see, this serum possessed a marked purpura-producing property.

Effect of Injecting Anti rat-plate Serum into Rats.

Rat 1.—Received on Sept. 29th 2·5 c.c. subcutaneously in dorsal region near root of tail (from test bleeding after second dose). Sept. 30th: Numerous minute skin hæmorrhages round the area of inoculation and along the tail. None elsewhere. Oct. 1st: The animal now moribund was killed with ether. Post mortem: A large oval skin hæmorrhage was found at site of inoculation, with smaller petechiæ at the periphery. Numerous hæmorrhages in skin of tail. *A few in pyloric portion of stomach.* No generalised skin purpura. The result, however, showed that the serum from this early test bleeding possessed the purpura-producing property.

Rat 2.—Received on Oct. 13th, 1914, 3 c.c. subcutaneously (from moribund rabbit after its fourth dose). Oct. 14th: A few petechiæ noted on skin of hind limbs. Oct. 15th: Animal not examined. Oct. 16th: Animal very ill and drowsy, was accordingly killed with ether. Post mortem: Beautiful generalised skin purpura. Large hæmorrhage in muscles of one fore limb, marked purpura of tail. *Several small hæmorrhages in pyloric portion of stomach.* Lymph glands bright red in colour. No hæmoglobinuria. No cataract.

Rat 3.—Received on Oct. 14th 4 c.c. subcutaneously. Oct. 15th: Cluster of small hæmorrhages near site of inoculation. Oct. 16th: More hæmorrhages in the neighbourhood. Animal very ill and drowsy. Oct. 17th: Rat dead. Post mortem: Generalised skin purpura. Red lymph glands throughout. *Petechiæ in pyloric portion of stomach and throughout a considerable part of the small intestine, also in cæcum and rectum.* Urine in bladder blood stained.

On the whole, the lesions in rat purpura are essentially similar to those met with in experimental guinea-pig purpura, except that cataract, so frequently found in guinea-pigs dying of the experimental disease, has not so far been noted in rats. As mentioned above, the effect of anti-rat red-cell serum was investigated on rats. No purpuric lesions resulted.

Action of Heterologous Anti-plate Sera.

The question of the specificity of these anti-plate sera is of importance, and at various times control experiments in settlement of this point have been made. Invariably the result has been that the animal does not respond to the heterologous anti-plate serum—e.g., only slight inconvenience and certainly no purpura follow the

---

[3] Dale, H. H., and Laidlaw, P. P.: A Simple Coagulometer, Journal of Pathology and Bacteriology, vol. xvi., p. 351.

It will be seen from the tables that while the red cells were very considerably affected, the blood plates were not appreciably altered in number The most striking phenomenon in connexion with this serum is the great but temporary fall in the absolute number of leucocytes In this fall, as the differential counts show, the polymorphonuclear cells are chiefly involved No hæmorrhages were seen on the skin during life or in the organs after death In both cases hæmoglobinuria was a well marked feature

Action of Anti red cell Serum (Ordinary Lytic Serum)

The effects of injecting lytic serum into the animal whose red cells have been used for immunisation have been studied by several workers, and notably by Muir and McNee (1912),[2] who have experimented with anti rabbit red cell serum prepared by immunisation of the goat with rabbit red cells No record has been found of the production of purpuric lesions by such sera It was, however, considered advisable to prepare a lytic serum for comparative tests, and for this purpose rabbits were immunised with washed guinea pig red cells in the usual way This serum has been tested on guinea pigs only in a few cases so far It is very lethal for guinea pigs, but no evidence has been obtained that it can give rise to generalised purpura As we shall see later, an anti rat red cell serum proved to be equally devoid of purpura producing effects when injected into rats, whereas the anti rat plate serum consistently produced purpura

The Question of Dosage of Anti plate Serum

To test this point four guinea pigs, each exactly 250 gm weight, received the following quantities of anti plate serum subcutaneously in the dorsal region on June 2nd, 1914 2 c c, 1 c c, 0 5 c c, and 0 1 c c (volume in all cases made up to 2 c c with saline) The animal which received 2 c c died on June 6th, showing an enormous number of hæmorrhages, with petechiæ on the heart and lungs and double cataract The animal which received 1 c c died on June 4th (i e, after 42 hours) There was beautiful miliary purpura over the whole skin, with petechiæ on the heart and lungs Cataract had not developed The animal which received 0 5 c c developed, like the others, a local swelling which had practically disappeared on June 6th It died ten days later, but showed no purpuric lesions either internally or externally Very probably any such lesions that may have occurred and escaped detection in the early days after inoculation had faded The animal which received 0 1 c c showed only very slight local swelling for a few days after inoculation, and remained well

Experimental Purpura in the Rabbit

An anti rabbit plate serum was prepared by immunising the goat with rabbit blood plates recovered from rabbit blood by a method similar to that employed in the case of guinea pig blood Each dose given to the goat consisted of the blood plates recovered from the mixed blood of 12 rabbits About nine such injections were given The serum of the goat was tested at various times during the course of immunisation, and it will be convenient to detail briefly the results obtained with this serum on various rabbits, as in certain cases highly interesting pathological lesions were found at necropsy In the earlier cases of the series purpuric lesions in the skin were unfortunately not searched for

Rabbit 1 —Received on June 20th 4 c c. anti plate serum subcutaneously (from test bleeding of goat after three doses) June 21st Considerable soft local swelling June 23rd Swelling very slight Rabbit remained well till July 15th, when sudden death took place Post mortem - Animal well nourished Peritoneal cavity filled with clotted blood and extravasated fæces *Two large fairly clean cut perforations of the bowel just below cæcum A few purpuric spots in small intestine Some faded purpuric spot in skin, especially that of hind limbs Large hæmorrhages in the psoas muscle and in the muscles over tibia and fibula Effusions of blood in the periosteal sheaths of these bones Stomach mucosa showed a cluster of minute hæmorrhages, but there was no general purpura of the organ* Liver and lungs healthy

Rabbit 2 —Received on June 20th 1 5 c c intravenously (test bleeding after four doses) Remained well

Rabbit 3 —Received on June 30th 2 c c intravenously (test bleeding after four doses) Remained well till July 3rd, when it was given a further dose of 3 c c intravenously Death occurred two hours thereafter Post mortem *Perforated ulcer of colon adherent by film of lymph to abdominal wall Purpuric patches round the ulcer* The colon contained another large ragged ulcer with greyish scurf on it It was not perforated *In the stomach were two similar large non perforated ulcers* Right lung collapsed and congested Some free blood in right pleural cavity The liver contained a few nodules of pseudotuberculosis so that some doubt remains whether the late purpuric lesions met with may have been of bacterial origin This is, however, unlikely

Rabbit 4 —Small Russian Received on July 6th 5 c c intraperitoneally (test bleeding after four doses) July 7th Three or four purpuric spots in skin over sternum July 8th Very large number of purpuric spots on skin of abdomen and back, and especially of extremities Petechiæ on ear On the same day it received a further dose of 3 c c intraperitoneally July 9th Rabbit looks well Received a third dose of 3 c c intravenously and died in convulsions five minutes afterwards Post mortem Enormous number of skin hæmorrhages Miliary purpura of stomach, One or two petechiæ on epicardium and a good number on large bowel and under kidney capsule Very large number in skin covering fore and hind extremities and tail No cataract. Large amount of free blood in peritoneal cavity One or two reddish lymph glands in axilla and groin Urine quite clear

Rabbit 5 —Very small Russian weighing 440 gm. Received on August 27th 4 c c intraperitoneally (test bleeding after seven doses) August 28th Animal looks fairly well Numerous purpuric spots on skin of abdomen and extremities Weight 431 gm August 29th Animal dead Post mortem Beautiful purpura of skin *Extensive purpura of cæcum and large bowel* A few spots in small intestine and in stomach Numerous petechiæ in diaphragm

Blood Changes in Experimental Purpura of the Rabbit

We append three tables (Nos IV A, IV B, and IV C) in which are recorded the blood changes, &c in the case of three rabbits inoculated intraperitoneally with the same dose (3 c c) of anti-rabbit plate serum

TABLE IV A —*Rabbit 33*

[2] Muir R. and McNee The Anæmia Produced by a Hæmolytic um Journal of Pathology and Bacteriology vol xvi p 410

appeared blurred except at the first moment of opening There was no doubling of objects, they seemed to "dissolve." He was crying the whole time and worrying as to whether he was going blind He kept *turning over* in his mind the succession of events from the beginning of the advance to the bursting of the shells At the dressing station he was still crying and shivering, he was taken thence to a hospital by horse ambulance, where he was given brandy, and then sent on by horse ambulance to another hospital, and thence by motor ambulance at night to X, where he arrived early on Nov 1st He thinks he must have slept on the ambulances as he *remembers nothing*

From Nov 1st to 4th at X, his eyes were bandaged and drops were instilled which "burnt terribly" No numbness or anæsthesia observed *Slight deafness* which soon passed off. On Nov 1st he shivered in bed almost incessantly, his thoughts were still running on events between the advance and the bursting of the shells No shivering after Nov 3rd. He says he *did not micturate* from Oct. 30th P M until Nov 2nd P M. and *did not defæcate* from Oct. 30th until Nov 5th (after aperient here) No involuntary passage of urine or fæces

Past history—He had been for two months in the Aisne district on the lines of communication, sleeping badly all that time owing to lumbar pains (and toothache during the first three weeks) He had failed to pass a medical examination some time previously because of renal trouble (abnormal amount of albumin in water) until after a long period of treatment He had had lumbar pains a few nights before coming to France

Present condition—*Nov 6th*—A well nourished man of nervous temperament, flushed complexion, and dark eyes Movements normal, skin sensations normal Eyes, fundi normal *Fields distinctly contracted*, especially on temporal sides Right eye—can read at normal distance but "things have a slight haze round them" Left eye—the haze is much greater, is unable to see letters until they are quite near

Nov 7th—Says he has lost his sense of taste and smell since the shells burst round him Gets up now

Nov 9th—Woke up last night and found himself crying, "not thinking of anything in particular", he at once "pulled himself together"

Nov 10th—Tested for *taste* (tongue protruded) and *smell* in order mentioned —

(1) Very strong sol. of sugar	Slightly sweet (only tasted after the tongue had been moved about)
(3) ,, ,, ,, salt	No taste
(4) ,, ,, ,, acid	No taste but "a peculiar feeling as if it dried the tongue"
(7) ,, ,, ,, quinine	No taste (later "a peculiar feeling of biting on the tongue")
(5) Carbolic acid (1 40)	No smell
(6) Ether	Faint smell like collodion
(8) Peppermint (strong)	Faint smell of peppermint.
(2) Tincture of iodine	No smell.

Hypnosis tried, patient explains later—"I insisted on resisting" *Suggestions* offered during concentration *Nov 13th*—Says his taste and smell are returning Fields of vision still restricted, perhaps slightly less so *Nov 15th*—He was transferred to England for further treatment

On Nov 16th the patient was admitted to the Middlesex Hospital London, under the care of Mr Arnold Lawson, who has kindly allowed me to append his note of the condition of the patient's eyes —

$$\text{Nov 25th}\quad \text{R E}\ \Big|\frac{+1\ 75}{+2\ 25},\qquad \text{L E}\ \Big|\frac{-1}{+2}$$

Visual acuity each eye 6 36, when under correction 6/18 Just below and to the outer of the left disc is a small clear buff patch in the choroid The upper inner margins of the discs are somewhat blurred and more densely white than elsewhere These features are probably not pathological The fields are definitely restricted especially on the nasal side of the retina being limited here to 40° in the right eye and to 70° in the left No central scotoma. Taste and smell were found affected on admission but these recovered earlier

Nov 27th—General condition improved Not so "nervy" Visual acuity under correction R E 6/24, L E 6/18 The patient is now (Feb 1st) attending the hospital as an out-patient

CASE 2—Corporal, aged 25 Admitted on Dec 11th, 1914 The patient says that he was buried for 18 hours on Dec 8th owing to a shell bursting and "blowing in" the trench in which he lay Can remember nothing until he found himself in a dressing station at a barn lying on straw. He says that then he could not see and that for this reason he fell over something when he got up and walked about there As to his past history, he came out to the war on August 13th, and was in the last two days' retreat at Mons and after at La Bassée Has slept very badly since the start, often when billeted taking large doses of whisky to procure sleep Has led a "fast" life and has had recent domestic worry

Present condition—*Dec 12th*—A healthy looking man with flushed face and large dark eyes with wide pupils His general manner does not inspire one with confidence in his reliability Complains of pains in abdomen, back and limbs, and of difficulty in seeing The pains are chiefly in the knees and ankles His *sight has been very indistinct* since he was "buried" Says that if he looks at an electric light it takes him "five minutes" before he can see anything again. His vision has much improved since Dec 8th, but he can only read when the type is close to his eyes and not for long, "it all becomes blurred" Heart, lungs, and joints appear normal Abdomen distended and tender in lower part *Bowels not opened for five days* Aperient is effective Vision R E 5/60 L E 2/60 Media clear Fundi natural[1] Pupils and eye movements normal. Hearing normal

Dec 17th—*Smell* Fails to smell peppermint, ether, iodine tincture, and carbolic acid (1 40). *Taste* (tongue protruded) Very strong solution of sugar—tasted only after movements of tongue are allowed. Very strong solution of salt—"feels like petrol does on the hand," tasted only after movements of the tongue are allowed. Solution of acid—"salty, like alum."

Dec 19th—Complains that he does not sleep, but the sister in charge of his ward says that he sleeps well. *Treatment by suggestion* (during and without hypnosis) was begun, and continued daily until patient's transfer to England. On the second trial and afterwards a state of light hypnosis was easily induced. The deeper stages, involving hallucinations, anæsthesia, and post-hypnotic amnesia, could not be reached on any occasion But the lighter stages (in which the patient responded to suggestions that he could not open his eyes, close his hand, stop laughing and the like) sufficed to bring about assurance of a good night's sleep, gradual restoration of memory, and (later) improvement in visual and olfactory acuity in near vision, in visual fields, and in colour sensibility The improvement in visual acuity and near vision is shown in the following table —

—	Visual acuity Both eyes.	Near vision.	
		Right eye	Left eye
Dec 15th	Before hypnosis, 5 60	No 15 Jaeger (badly)	Less than No 15 Jaeger
, 23rd.	After ,, 3/36.	No. 12 Jaeger	No 15 Jaeger (badly)
, 26th.	Before ,, 1/6	No 6 ,,	No 12 Jaeger
	After —	No 4 ,,	No 10 ,,
, 27th.	, 2/6.	No 2 ,,	No 10 ,
28th.	No 4/6	No 1 ,	No 4 ,,

---

[1] Colonel W T Lister A.M.S., reports (Dec. 15th) that under homatropine and cocaine the refraction of the patient's eyes is as follows:

$$\text{R.E}\ \Big|\frac{+2\,5}{+2\,5}\qquad \text{L E.}\ \Big|\frac{-1?}{0\ \text{or}\ -0\,5}$$

He makes at the same time the following note on the fundi "Right eye Sector below disc is deficient in retinal pigment so that the choroidal vessels are abnormally visible but there is no pathological pigmentation and there are no areas of atrophy Left eye Internal crescent vessels drawn to nasal side and lack of retinal pigment on nasal side (nasal staphyloma) The atrophic appearance is more marked in this eye even the choroidal pigment is deficient, giving a pale area. Macula normal. Both discs are pale, and there is connective tissue by the sides of the vessels. The whole condition in my opinion, might be congenital."

injection of the guinea pig with anti rabbit-plate serum, and *vice versâ* Recently, being in possession of a supply of anti guinea-pig plate, anti-rabbit-plate, and anti rat plate sera, one of us has carried out the following experiment, which shows clearly that a heterologous anti plate serum has no purpura producing property

TABLE V

Rat A	150 gm	received 7/12/1914,	3 c c	anti rat plate serum
„ B	90 „	„ „	3 „	anti guinea pig plate serum
„ C,	140 „	„	4 „	anti rabbit plate serum

(All inoculated subcutaneously)

Guinea pig A	230 gm	received 7/12/1914	3 c c	anti guinea pig plate serum
„ B	230 „	„ „	3 „	anti rat-plate serum.
„ C	230	„ „	4 „	anti-rabbit plate serum

(All inoculated subcutaneously)

Rabbit A,	400 gm.	received 7/12/1914	4 c.c.	anti rabbit-plate serum.
„ B,	380 „	„ „	4 „	anti guinea pig plate serum
„ C,	380 „	„ „	4 „	anti rat plate serum

All inoculated intraperitoneally)

On Dec 8th Rat A showed several purpuric spots near tail and also on legs Other two rats showed nothing and appeared quite lively Guinea pig A had an extensive hæmorrhagic infiltrate over the whole of the abdomen and did not appear well The other two animals showed no purpura and were quite lively Rabbit A had numerous purpuric spots all over its skin and was obviously ill The other rabbits were quite lively and showed no purpura On Dec 9th the animals inoculated with the homologous sera were still more drowsy and listless Other animals appeared quite well On Dec 10th Guinea pig A and Rabbit A dead

Post mortem Guinea pig A showed beautiful skin purpura, extensive œdematous and hæmorrhagic infiltrate spreading over abdomen from seat of injection and extending deeply into the thigh muscles, and miliary purpura of stomach There was no cataract, and the urine was quite clear Rabbit A showed a large œdematous and hæmorrhagic subcutaneous area over upper thorax, neck, and fore limbs also a larger hæmorrhage under skin of left cheek. Miliary purpura of stomach and slight purpura of intestine. Liver yellow and mottled No cataract Urine quite clear

The other animals remained well and put on weight

Dec 11th Rat A dead. Post mortem Purpura of skin particularly marked over skull and cheek A few spots in pyloric portion of stomach and a few in small intestine Urine was blood stained (hæmoglobinuria)

The other animals, which received the heterologous plate sera, remained well and put on weight

Summary and Conclusions

1 Data have been recorded on the blood changes in guinea pigs after inoculation with anti guinea pig plate serum The early fall in the number of platelets simultaneously with the outburst of skin purpura is found to be a marked feature

2 Purpura has also been produced in rabbits and rats by inoculation with the respective anti plate serum The blood changes in rabbits have been followed with results similar to those obtained in guinea pigs

3 Anti plate serum, in addition to its purpura producing properties, possesses in common with other cytolytic sera considerable lytic powers, which in all probability contribute largely towards the fatal issue in small animals Death, however, may occur as the result of extensive hæmorrhages alone without any obvious lytic changes as evidenced by hæmoglobinuria

4 Sera obtained by immunisation with red cells or leucocytes do not produce purpura

5 Purpura is not produced by inoculating animals with heterologous anti plate sera.

The histology of the purpuric lesions will form the subject of a later communication.

A CONTRIBUTION TO THE STUDY OF SHELL SHOCK.

BEING AN ACCOUNT OF THREE CASES OF LOSS OF MEMORY, VISION, SMELL, AND TASTE ADMITTED INTO THE DUCHESS OF WESTMINSTER'S WAR HOSPITAL, LE TOUQUET

BY CHARLES S MYERS, M D, Sc D CAMB,
CAPTAIN, ROYAL ARMY MEDICAL CORPS

THE remarkably close similarity of the three cases which are described in this paper is shown in the following synopsis —

—	Case 1	Case 2.	Case 3.
Cause	Shells bursting about him when hooked by barbed wire	Shell blowing trench in	Shell blew him off a wall.
	Preceding period of sleeplessness.	As in Case 1.	?
Vision	Amblyopia. Reduced visual fields	?	As in Case 1
Hearing	Slightly affected for a brief time	Not affected.	As in Case 2.
Smell	Reduced acuity	Total anosmia	Unilateral anosmia and parosmia.
Taste	Almost absent	Reduced acuity	As in Case 2.
Other sensations	Not affected.	As in Case 1	As in Case 1.
Volitional movements	„	„	„
Defæcation	Bowels not opened for five days following shock		?
Micturition	Urine not passed for 48 hours	Not affected	As in Case 2.
Memory	Apparently slightly affected	Very distinct amnesia	„
Result of treatment	Gradual improvement by rest and suggestion	As in Case 1 supplemented by hypnosis	As in Case 1

CASE 1 —Private, aged 20 Admitted on Nov 5th, 1914 On the nights of Oct 28th and 29th he slept in the booking hall of X station, "not much sleep there" On the 30th he motored in a bus from X to Y, arriving there at 7 30 P M, billets found at 8 P M, on guard from 10–11 30 P M, and from 1 45–3 45 A M At 11 A M on the 31st for the first time he went to the firing line His platoon advanced to one set of trenches and then crossed the road to another, only to find it filled with cavalry and to be told that there was no room for them During the retirement from this trench, at 1 30 P M, they were "found" by the German artillery Up to that time he had not been feeling afraid, he had "rather been enjoying it," and was in the best of spirits until the shells burst about him

He was now retiring over open ground kneeling on both knees and trying to creep under wire entanglements when two or three shells burst near him As he was struggling to disentangle himself from the wire three more shells burst behind and one in front of him (An eye-witness in this hospital says that his escape was a sheer miracle) After the shells had burst he succeeded in getting back under the wire entanglements, all his comrades had retired already He managed to get into a trench and as the firing slackened he rejoined his company Immediately after the shell had burst in front of him his sight became blurred It hurt him to open his eyes, and they "burned" when closed. The right eye seemed to have 'caught it" more than the left At the same moment he was seized with shivering, and cold sweat broke out especially round the loins He thinks the shell behind him gave him the greater shock—'like a punch on the head without any pain after it.' The shell in front cut his haversack clean away and bruised his side and apparently it burned his little finger It was this shell he says, which 'caused his blindness"

Falling in with two comrades he was led by them one on either side, to the dressing station He opened his eyes occasionally to see where he was going but everything

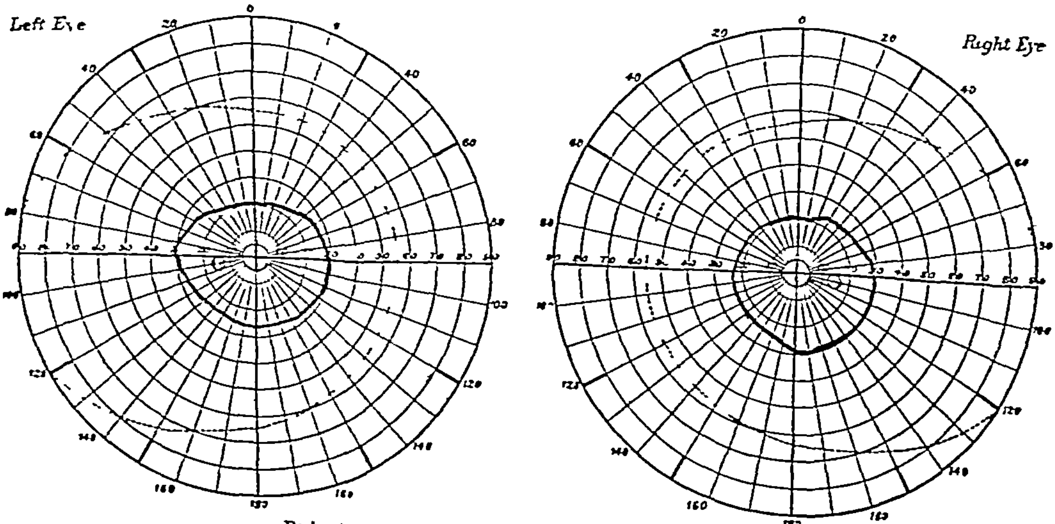
To recover the memory of this period other methods, in addition to hypnosis, were vainly tried His dreams were generally of incidents belonging to earlier periods of the war, never of the trench-shelling Attempts to obtain revival of the lost memories by getting him (*a*) to concentrate his attention on the scene of the shell bursting or of the N dressing station, or (*b*) to record his thoughts when in a state of reverie, were fruitless

How far the patient's memory, so far as it returned, can be trusted is not altogether certain A man of the same regiment happened to be warded here at the time He believes that the patient could not have remained in the trench for longer than an hour after the shell had burst He declares that he saw him get out of the trench and report himself sick to Corporal R, and that he heard Corporal R tell the patient to go off on foot to the M dressing station. Until the day after the patient's arrival at the barn he never saw the patient again, when he was brought in himself there He says that the doctors at the barn considered the patient "off his head" He does not believe that the N Regiment was anywhere in the neighbourhood. He says that the man K. had been mortally hit some days before

On further examination the patient says he has no recollection of reporting himself to Corporal R or of meeting his fellow patient while at the barn, and he is quite certain that *somehow* he reached the N s dressing station before he got to his own.

On the other hand, another fellow patient here happened to belong to the N Regiment and was able to confirm the patient's account by stating that the trenches of the N Regiment were on that day immediately next to those of the M Regiment and that the N and M. dressing stations were situated in the same village, the former in a cottage about three quarters of a mile beyond the latter, so that one would have to pass the M dressing station on the way from the trenches to the N dressing station

CHART 2.



Perimeter charts from Case 3 showing contraction of fields.

There is hence a possibility that the patient wandered in a state of somnambulism from the trench past his own dressing station to that of the N s or that he wandered first into the N trenches and was then brought, as he avers, to the dressing station by men of the N Regiment But of this last point the patient is not now so certain. He still insists that a man stepped into his fallen trench on top of him.

On Dec 30th the patient was transferred to England for further treatment, and on the 31st he was admitted to the London Temperance Hospital under the care of Mr J S Hosford, whence he has, I understand, now been discharged.

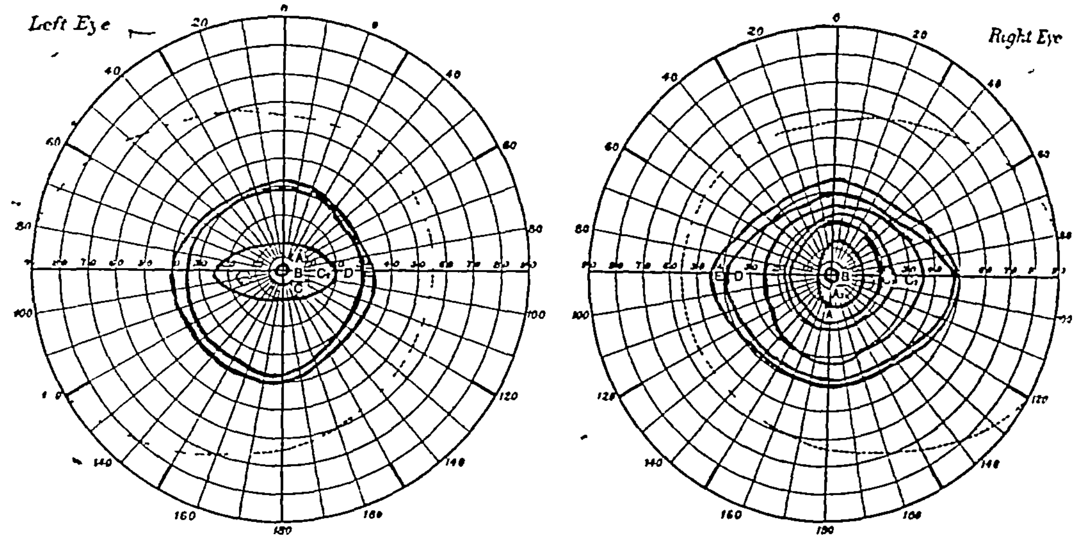
CASE 3 —Private aged 23 Admitted on Jan 26th, 1915 The patient says that he was blown off a heap of bricks 15 feet high owing to a shell bursting close to him. Thinks he must have fallen into a pool of water, as he next remembers finding himself, about 3 P M. the same afternoon in a cellar near a church with his clothes drenched. He does not know how he got there or how he left the cellar, but he remembers being in another hospital before he was admitted here He cannot say if anyone was in the cellar with him He remembers someone in the train talking to him and reminding him of being in the cellar

Present condition —Jan 27th —A healthy-looking man, well nourished but obviously in an extremely nervous condition He complains that the slightest noise makes him start. His legs feel weak, and he has pain in the precordial region His *sight has been very much impaired* since the shock. Distant vision he says is affected, and objects and type become blurred when long looked at He has slept very little the last two nights Heart lungs and joints appear normal. Abdomen general spasm of muscles of wall on being touched. Hands tremulous. Knee jerks normal but the first attempts to evoke them provoked a spasm of the calf muscles and a few general convulsive movements as the patient lay in bed. His hands became very tremulous and his forehead sweated profusely He appeared as if about to faint and says that he felt cold and dizzy and experienced "round and round movements of the stomach" The slightest touch on the legs provoked well marked spasm of the quadriceps muscles of the same thigh. Plantar reflexes not obtainable. Extensor muscles of the toes appeared to be in a state of tonic contraction

Jan 30th —Slept well last night for the first time *Bowels not opened for five days* since the shock. Took an aperient last night and this morning, bowels open to-day *Eyes* Fundi normal. *Fields, distinctly contracted* as in Chart 2. Near vision, either eye, No 14 Jaeger, less for short words Visual acuity (investigated by Colonel Lister, A M S)—at first 6/24 but improved by encouragement and the indiscriminate use of weak + or − lenses to nearly 6/6

The improvement in visual fields is shown on the annexed Chart 1[2] The "functional" character of this restriction of fields is shown by the fact that the patient was never observed to collide with objects when walking, and that he was able to box here when convalescent

CHART 1.



Perimeter charts from Case 2. A Dec 14th A_1 at start A_2 after testing other eye B Dec 21st C Dec 26th C_1 before hypnosis C_2 after hypnotic suggestion D Dec 27th E, Dec 28th.

The improvement in *colour sensibility* was as follows — Dec 14th Half inch square of colour recognised at 22 cm R E, 7 5 cm L E Dec 27th 350 cm R E 50 cm L E The sensibility of the eyes to red appeared to be keener than that to any other colour Thus the red square was recognised at 100 cm by the left eye on Dec 27th, while other colours (yellow, blue, and green) could only be recognised at 50 cm So, too, on Dec 14th the visual field for the recognition of coloured squares was limited in both eyes to the fovea save in the case of red, the field for which in the right eye extended definitely, though slightly, beyond the fovea towards the nasal side of the retina

The improvement in *olfactory acuity* is shown by the fact that on Dec 27th he was able to smell and to recognise ether, peppermint, camphor, and turpentine, although still unable to smell carbolic acid (1 10), tincture of iodine, or methylated spirit

The gradual restoration of *memory* occurred as follows —

Dec 22nd —During hypnosis suggestions made evoked a description of how the ground fell in on him at the trenches He says that he was buried up to the neck and that Sergeant L dug him out Men of the N Regiment (not of his own regiment) took him to their dressing station, but the medical officer there "packed him off" to the dressing station of the M (his own) Regiment He can now remember Captain S (attached to his regiment from the ——) speaking to him and giving him a drink He spoke to him when he reached the barn (the M 's dressing station) While under hypnosis the patient is told that he will remember this when he awakes He does so but cannot explain why he had not been able to recall it before

Dec 23rd —To-day *before hypnosis* he remembers another "big hospital" to which he was taken on leaving the barn—a "big square room with a stove in the centre"—opposite which he was placed But he cannot recall how he got there, or how he left to come here by train He cannot remember being carried on a stretcher until they took him out of the train at Étaples (the railway station for this hospital) He says that there was 'no light' in the barn all the time he was there (24 hours) He remembers struggling in the trench 'for hours" after he was buried Finally he gave it up "I went to sleep and was enjoying myself at home when they started 'messing me about Someone fell on me and woke me up I 'tumbled to things a bit' when they got me out I got up and then fell down and it was all a 'wash out.'"

Under hypnosis he confirms the above, adding that in his struggles in the trench he "said a prayer or two" and that when he fell asleep he thought himself in the R Hotel at S where he had lived for years and is well known 'I was listening to a young lady I know [not intimately] playing the piano I saw Mr S [the landlord] and Mrs S The sleep and dreams kept coming and going It was dark when they dug me out After I got out a chap said 'the fellow s mad' and I said 'You re a liar' Now, I remember a place between the barn and the hospital rather a smart building, a long, low place I was on a stretcher there I must have got there by a horse ambulance but I cannot remember this"

Dec 26th —Before hypnosis he recalls going to the clearing hospital (just mentioned) from the barn in a horse ambulance on a stretcher at midnight He says "I can remember talking to a major the next morning and having a sleeping draught at night Then I went to another hospital at B I had a ride in a motor ambulance on a stretcher, but whether this was from or to that hospital I cannot remember I remember the journey in the train here distinctly There were continual offers of tea cocoa sweets, and cigarettes They wouldn t let us sleep for these things I had a bad headache all the way down from the trenches I did not bother much about my sight, as I thought it was imaginary It wasn't until I got rid of the pain in my stomach which I came in with that I began to find my sight wouldn t let me read"

Dec 27th —While in hypnosis he gives the name of the man in the same trench with him as K He "sees very clearly the position of the trenches their shallowness and covering He remembers that he had been two days in the reserve trenches before he was sent on Dec. 7th to the firing line He says, ' The explosion lifted us up and dropped us again It seemed as if the ground underneath had been taken away I was lying on my side, resting on my hand when the shell came I got my right hand loose but my left was fixed behind a piece of fallen timber At last I dropped off to sleep and had funny dreams of things at home One dream in particular I have thought over many times since I haven't been able to make out why I should dream of the young lady playing the piano I don t know her name and don t think I have seen her above twice"

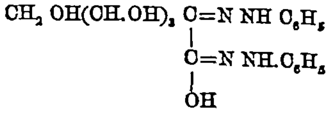
Dec 29th —Before hypnosis he says that he can now "see" the N s dressing station—a one storeyed house with two non communicating rooms He was taken first into the left-hand room, and later into the other in which the medical officer sat No further information obtainable *under hypnosis* He cannot recall how he got to the N s dressing station from the trenches with water, alcohol and ether, and dried The calcium content of the salt prepared in this way was determined in 6 cases with the following results (i.) 9 4 per cent, (ii) 9 5 per cent, (iii) 9 2 per cent, (iv) 9 3 per cent, (v) 9 4 per cent, and (vi) 9 6 per cent., an average of 9 4 per cent., which corresponds closely to the theoretical calcium content, 9 39 per cent., of a salt with the formula $(C_6H_9O_7)_2$ Ca.

---

[2] My thanks are due to Colonel Lister A M S who by presenting the hospital with a portable perimeter and test types made these observations now possible

To separate the free acid from the calcium salt it was suspended in water and a stream of carbon dioxide gas passed through for two hours The calcium carbonate precipitate was then filtered off, and the filtrate concentrated by evaporation *in vacuo* over sulphuric acid A thick, yellowish, hygroscopic syrup, from which no crystals separated, even after several months, was obtained It had a sweetish acid taste, was lævorotatory, fermented with brewer s yeast, rapidly reduced alkaline solutions of copper and bismuth, and gave both Seliwanow's and Pinow's tests

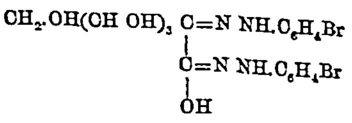
The phenylosazone and parabromphenylosazone were then prepared by the method of Maquenne, and the melting point determined on the "bloc Maquenne" The phenylosazone separated out as rather coarse yellow crystals arranged in sheaves The purified product in all the cases examined had a melting point of 223° C, which is 7° lower than the melting point of dextrosazone and lævulosazone The percentage of nitrogen in the osazone was determined in two cases by Dumas s method, giving in one instance 14 80 per cent and in the other 14 99 per cent These results suggest that the formula of the compound is probably—



$$\begin{array}{l} CH_2\,OH(CH.OH)_3\,C{=}N\,NH\,C_6H_5 \\ \qquad\qquad\qquad\quad\ \ | \\ \qquad\qquad\qquad\quad\ \ C{=}N\,NH.C_6H_5 \\ \qquad\qquad\qquad\quad\ \ | \\ \qquad\qquad\qquad\quad\ \ OH \end{array}$$

—with a theoretical yield of 14 97 per cent of nitrogen.

The parabromphenylosazone was obtained as fine yellow felted needle-like crystals In 4 cases of simple "lævulosuria" it was found to have the following melting points (i) 196° C, (ii.) 197°, (iii.) 197°, and (iv) 198° While in 5 cases in which the substance had been isolated from the urine of diabetics in which dextrose was also present the following results were obtained (i) 198° C (ii) 197° (iii) 198°, (iv) 198°, and (v) 196° The close correspondence of the melting points in diabetic and non-diabetic cases suggests that the lævorotatory substance is the same in both The percentage of nitrogen present in the parabromphenylosazone was determined in two of the cases, one yielding 10 56 per cent and the other 10 40 per cent., results which correspond to the theoretical yield of 10 52 per cent. for an osazone with the formula—

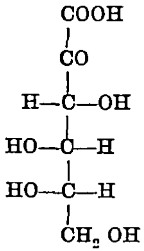


$$\begin{array}{l} CH_2.OH(CH\,OH)_3\,C{=}N\,NH.C_6H_4Br \\ \qquad\qquad\qquad\quad\ \ | \\ \qquad\qquad\qquad\quad\ \ C{=}N\,NH.C_6H_4Br \\ \qquad\qquad\qquad\quad\ \ | \\ \qquad\qquad\qquad\quad\ \ OH \end{array}$$

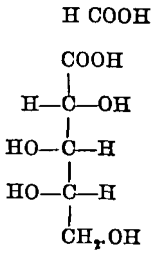
It will thus be seen that the melting point and nitrogen content of the phenylosazone and parabromphenylosazone do not correspond to the osazones formed by true lævulose, but that they point to the lævorotatory substance which occurs in the urine, both in diabetic and non diabetic cases, being a ketonic acid To confirm this a study of its oxidation products was undertaken.

10 c c of the syrup prepared in the manner previously described were dissolved in 100 c c of water and heated with 20 grm of lead peroxide and 10 grm. of sulphuric acid on a water bath for three hours The mixture was then cooled and filtered The filtrate was treated with barium carbonate until the acid was neutralised then boiled and filtered The filtrate was shaken with animal charcoal filtered concentrated to 50 c c and mixed with 100 c c of absolute alcohol After standing for four hours the mixture was filtered The precipitate was then washed with absolute alcohol, dried, and the barium content determined 0 7428 grm was found to give 0 3718 grm of barium sulphate corresponding to 29·46 per cent *of barium* for the original compound This yield corresponds within the limit of experimental error, to the theoretical yield of 29·40 per cent. of barium for barium arabonate $Ba(C_5H_9O_6)_2$, the oxidation product produced by the action of lead peroxide on an acid of the formula, $CH_2\,OH\,(CH.OH)_3\,CO\,COOH$

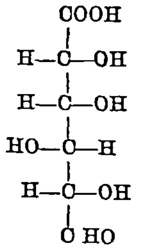
To confirm the presence of arabonic acid a portion of the salt was dissolved in water and the barium precipitated by carbon dioxide gas, the excess of which was subsequently removed by boiling After filtering off the precipitate of barium carbonate, the solution was evaporated *in vacuo* over sulphuric acid In five days white crystals appeared, and these were found to have a melting point of 97° C corresponding to that of arabonolactone These results pointed to a structural formula of—



Isoglucuronic acid.



Arabonic acid.



Glucuronic acid

This substance, from its analogy to glucuronic acid, we propose to name isoglucuronic acid.

In the course of our investigations we have examined specimens of urine from 30 cases of so called lævulosuria and 50 of diabetes, in which a lævorotatory substance was present along with the dextrose, but in none of them could any true lævulose be found, the lævorotatory body in each instance being proved to be isoglucuronic acid The data upon which a diagnosis of lævulosuria has been based in most of the published cases are such that the results obtained might equally well be explained by the presence of isoglucuronic acid, for the reduction of Fehling's solution, a positive Seliwanow's reaction, lævorotation, these properties being abolished by previous fermentation with yeast, and the formation with phenylhydrazine of an osazone which has the melting point of glucosazone are characters shared by both bodies

In some of the more recent cases reliance has been placed upon the formation of a crystalline calcium compound and the separation of a methylphenylhydrazine derivative with a melting point of 153° C, but, as we have shown, isoglucuronic acid forms an insoluble compound with calcium, and we have found that with methylphenylhydrazine it yields an osazone which melts at 150° C The difference between the two melting points is so slight that it cannot be relied upon as a means of differentiating the substances, especially as we have found that the melting point of methyl phenyllævulosazone is not very sharp and is consequently difficult to determine with certainty That this is the case is also suggested by the fact that melting points of 153° C,[3] 159° C,[4] and 158°–160° C[5] for the compound are given in recognised text-books In support of our contention that isoglucuronic acid and lævulose are distinct substances, it may be mentioned further that a mixture of equal parts of the methylphenylosazones prepared under identical conditions has been found to melt at 120–130° C on the bloc Maquenne," whereas the osazone of lævulose melts at 162° C and that of isoglucuronic acid at 155° C The only published case in which it seems to have been conclusively proved that lævulose was present in the urine is that described by Otto Neubauer,[6] for in this instance the sugar was isolated in a crystalline

[6] Münchener Medizinische Wochenschrift, 1905, Band lii 1525

Smell Has complained until to day of a *subjective sensation* of the odour of cordite. This has left him "since the bowels were open" *Left nostril fails to detect* smell of ether, peppermint, eucalyptus, ammonia, carbolic acid, or iodine tincture, all of which, save the last, are at once recognised when placed beneath the right nostril No signs of nasal obstruction *Taste Only tastes very strong* solutions of sugar, salt, and acid, and then only when the tongue has been withdrawn and moved about the mouth, the taste is described as "*faint*"

Feb 1st—He complains that he gets very excited when anyone addresses him He still fails to remember how he got to the cellar, but he now remembers someone there asking him his name and regiment He says 'When I got into the hospital before I came to this one I can now remember being put against a wall and then being taken into a small room to see the doctor, who gave me a ticket and told me I was suffering from concussion I think I must have gone to sleep after this, as I don't remember anything else until I was in the train There a Royal Army Medical Corps bearer brought me a German prisoner to talk to He was in the Bavarian Guard and had just seen his first action

[Patient is still under treatment]

Comment on these cases seems superfluous They appear to constitute a definite class among others arising from the effects of shell shock The shells in question appear to have burst with considerable noise, scattering much dust, but this was not attended by the production of odour It is therefore difficult to understand why hearing should be (practically) unaffected, and the dissociated "complex" be confined to the senses of sight, smell, and taste (and to memory) The close relation of these cases to those of "hysteria" appears fairly certain

I have to thank Captain W P S Branson and Captain H Pritchard, R A M C, in whose wards these patients were placed, for permission to make these investigations, and Major Gordon Watson, R A M C, Commandant, for permission to publish them

THE PSEUDO-LÆVULOSE OF DIABETIC AND OTHER URINES

BY P J CAMMIDGE, M D LOND,

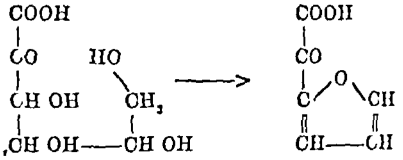
AND

H A H. HOWARD, B Sc

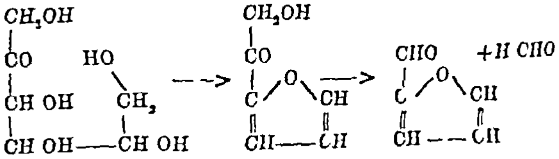
IN a previous paper[1] we pointed out that the lævulose usually met with in urine, unlike the lævorotatory sugar of plant origin, is precipitated from acid solutions by basic lead acetate, resembling in this respect glucuronic acid This observation appears to have been first made by Külz, who published in 1890 a paper[2] giving the result of his analyses of the so called urinary lævulose Like plant lævulose, this substance reduces copper and bismuth in alkaline solutions, is lævorotatory, and is fermented with brewer's yeast Külz also found that with phenylhydrazine it gave an *osazone* which in appearance, melting point (205° C), and on analysis corresponded to dextrosazone According to his analysis it has a formula nCH_2O Unlike plant lævulose, however, it could not be obtained in a crystalline form, but was only secured as a syrup The rate at which it reduced copper solutions, its rapidity of fermentation, and its specific rotatory power, but above all the ease with which it was precipitated by hydrates of the heavy metals, further suggested that urinary and plant lævulose were not identical substances Other workers have since published similar results, but no attempt appears to have been made to establish the exact nature of the substance

In diagnosing lævulosuria reliance has been placed upon a generally positive reaction with Seliwanow's test and the different readings obtained by reduction and the polarimeter Borchardt, using a modification of Seliwanow's test, has claimed that lævulose does not *occur in the urine, and that* previous statements to the contrary were due to want of care in testing for it In his modification the urine is treated with hydrochloric acid and *resorcin, made alkaline* with *sodium carbonate*, and then extracted with ethyl acetate On carrying out this test with a solution of plant lævulose the ethyl acetate extract is coloured red, but with urines giving the ordinary Seliwanow reaction the watery solution retains the pigment and the extract is yellow

These results obtained with Borchardt's test would be explained if, instead *of* lævulose, an acid with the *constitution*, $CH_2OH\,(CH\,OH)_3\,CO\,COOH$ were present The reaction would then be—



—and *this derivative being* a ketonic acid would dissolve in the sodium carbonate solution and not be extracted by the subsequent treatment with ethyl acetate *If, however, lævulose* were *present the following reactions would occur* —



—and the furfuryl derivative being *non* acid in character would not be soluble in the sodium carbonate solution, and hence would be extracted by the ethyl acetate Since the unmodified Seliwanow and Pinow reactions are readily *obtained in* a considerable number of cases, and in view of Borchardt's claim that true lævulose never occurs in the urine when tested *for* by his method, it seemed to us *that the so called* lævulose might be *the hitherto* undescribed ketonic acid, of which we have just given the formula This formula would explain its resemblance to glucuronic acid with respect to lead acetate, and would also admit *of the formation* of an insoluble calcium salt and a characteristic methylphenylhydrazine derivative

In order to investigate these *points* and to establish *the identity* of the substance specimens were prepared by the following procedure —

The urine was concentrated to a fifth of its volume and a saturated solution of lead acetate added using *one-tenth of the original* volume of urine taken The mixture was then heated on a water bath at 90° C, cooled filtered and the precipitate washed with water The precipitate was suspended in 100 c.c. of a saturated solution of sodium sulphate and digested for two hours when it was diluted to 500 c.c., filtered and the filtrate tested for lead When all the lead was found to have been removed the filtrate was mixed with 50 c c of saturated calcium chloride solution and 50 c c. of lime water After standing for two hours the precipitate that had formed was filtered off well washed

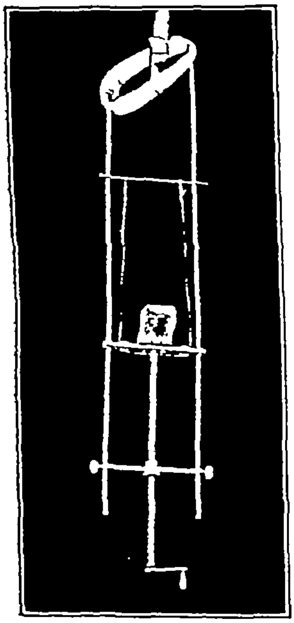
A NOTE ON THE TREATMENT OF GUNSHOT WOUNDS OF THE FEMUR

BY CUTHBERT WALLACE, M B, B S LOND, F R C S ENG,
SURGEON TO ST THOMAS'S HOSPITAL, LONDON AND MAJOR, R.A.M.C BRITISH RED CROSS HOSPITAL, NETLEY

A LITTLE time ago Mr B C Maybury and myself devised a modification of Thomas's knee splint with the idea of producing powerful extension of the leg during the process of plating fractures of the femur or tibia. When the Red Cross Hospital at Netley was opened the difficulty of adequately treating compound fractures of the femur was soon apparent The chief difficulty was in maintaining extension and at the same time providing for efficient dressing and (possibly more important) the comfort of the patient It was determined to try this modified Thomas's splint The result more than came up to expectations, and cases which arrived with bad wounds and suffering great pain during the process of dressing were soon put at their ease and improved rapidly In addition to this, some cases which were admitted six weeks after the injury with 3 inches of shortening were soon restored to their normal, or nearly normal, length, and union in a good position resulted

A short description of the splint (Fig 1) may be of service to those in charge of other hospitals The splint as made consists of the original Thomas's crotch ring with a lateral diameter of 9½ inches The two side pieces are made of mild steel, are parallel, and 8 inches apart Sliding on these parallel side pieces are two transverse bars The upper one is fitted with an ordinary footpiece The lower one is perforated to accommodate a large machine cut screw The top of the screw runs in a collar in the transverse footpiece

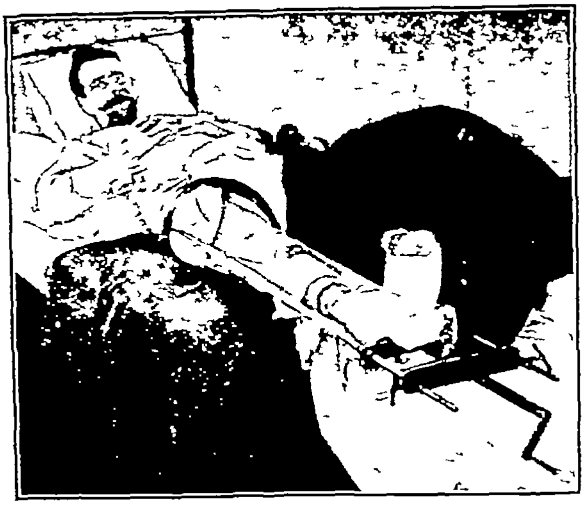
FIG 1.



The splint unapplied Shows the method of obtaining extension by means of a pin Note the wire fastened by rings to the pin and passing over the pulleys in the transverse bar that carries the footpiece The traction screw is longer than is now used.

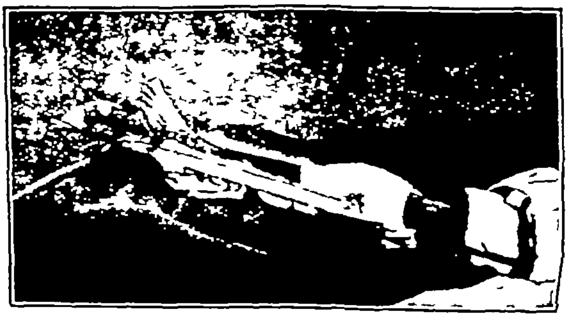
The process of application is as follows The ring is slipped over the foot and adjusted in the ordinary way, care being taken that the inner and back part of the ring gets a bearing on the tuber ischii. As the ring is rather large this is ensured by putting a pad on the outer side of the thigh The foot is then fastened to the footpiece by a stirrup extension or a leather anklet, or by webbing embedded in plaster put on over wool wrapped round foot and ankle The limb is supported in the splint by the two parallel bars in the same way that is usual in the Hodgen splint The lower transverse sliding piece is then fixed to the two parallel bars by screws provided for the purpose, and extension applied to the limb by turning the traction screw The end of the splint is either rested on sandbags or swung by a chain from a masthead or from the roof of the hut (Fig 2) By this means the patient is free to move about in bed within reasonable limits, and the dressing of a posterior wound can be effected without discomfort to the patient by either raising the splint or turning him on one side, the constant steady pull of the screw preventing any undue shifting of the limb and consequent pain to the patient If the limb tends to sag when the patient is turned on his side it can be prevented by loops of bandage fastened to the uppermost bar (Fig 4)

FIG 2.



The splint applied to a fracture in the lower third of the femur The splint is slung to the roof of the hut by a chain. Note the small pillow under the outer side of the ring The man's face is expressive of his comfort.

FIG 3



The splint applied to a fracture in the middle of the femur A pin has bee driven through the bottom of the shaft of the bone and extension produced by a chain. The man's foot had been injured by a bullet, so that a strapping extension could not be applied.

In those cases in which it is impossible to apply the stirrup extension, either because of the state of the skin or from the presence of wounds in the leg, a pin can be driven through the lower end of the femur and the extension applied by a chain or thick picture wire, which runs from one end of the pin down to the transverse footpiece over two pulleys let into this, and up again to the opposite end of the pin The use of the pulleys is to allow form, which is impossible with isoglucuronic acid Moreover, the crystals were found to be soluble in absolute alcohol, but were insoluble in a saturated alcoholic solution of lævulose

While therefore true lævulosuria, or fructosuria, may be met with it is apparently a rare condition, and in the majority of cases it seems probable that the term is a misnomer, and that the lævorotatory reducing substance that occurs in the urine is in reality the ketonic acid, isoglucuronic acid, we have described ' This is differentiated from lævulose by Borchardt's test, by being precipitated from an acid solution by saturation with lead acetate, and the melting point of the parabromphenylosazone

DEATH FROM STRANGULATED INTERNAL HÆMORRHOIDS

By P LOCKHART-MUMMERY, F R C S Eng,
SENIOR SURGEON, ST MARK'S HOSPITAL SENIOR SURGEON, THE QUEEN'S HOSPITAL FOR CHILDREN HONORARY SURGEON KING EDWARD VII'S HOSPITAL FOR OFFICERS

AND

M K JOSHI, M R C S Eng, L R C P Lond,
HOUSE SURGEON, ST MARK'S HOSPITAL.

INTERNAL hæmorrhoids are an extremely common complaint, but although they give rise to a considerable amount of discomfort and inconvenience, and even disability, it must be very rarely that they are the direct cause of death Cases of death from embolism following thrombosis of varicose veins in the leg are not uncommon, but a fatal issue from thrombosis of veins in the rectum is, in our experience, a very rare event It is obvious that the danger of embolism resulting from thrombosis of the rectal veins is not so serious as when the veins of the leg are involved, for whereas the latter veins drain direct into the general circulation, and consequently the detached portion of clot can reach the heart, in the case of thrombosis of the rectum the embolus is more likely to be in the liver, where it would not have such serious consequences

A case is recorded in THE LANCET of Sept 23rd, 1911, by Dr David A Alexander of portal pyæmia following thrombosed internal piles This patient had all the symptoms of portal pyæmia—rigors, ascites, œdema of the legs and abdomen, and a high temperature The patient was very seriously ill for a period of six months, after which he appeared to recover, only to have a relapse three months later, from which, however he again recovered The only cause for the portal pyæmia that could be found was a limited tract of thrombosis in the hæmorrhoidal veins

The following case, which was under our care at St Mark's Hospital, is evidently of a similar nature, but unfortunately ended fatally Although we think there was portal pyæmia in this case it was not so marked as in Dr Alexander's case The patient died apparently from septicæmia, the result of extensive gangrene of the rectum and neighbouring tissues, but had he survived longer we have very little doubt that the typical abscesses in the liver would have been evident The only treatment which would appear to have given the patient any chance of recovery was an early colotomy, which would have enabled the bowel to be kept clear of fæcal material It was, however, obviously unjustifiable to perform colotomy for thrombosed veins in the rectum, and by the time it was obvious that the whole of the rectum was gangrenous it was too late for this method to have had any chance of success, while the patient was certainly too ill to undergo any operation. The following are the notes of the case

The patient, a man aged 43 was admitted to St Mark's Hospital on Nov 14th, 1914, for internal piles He stated on admission that he had suffered from internal piles for about 25 years, and that of recent years the piles had prolapsed readily when he walked or on the least exertion and that they had to be replaced There had also been considerable bleeding at times Within the last few years he had had "several attacks of piles" which had necessitated his remaining in bed for some days The piles had evidently become strangulated during these "attacks," and he had been unable to replace them

The patient was very much afraid of an operation and he had put off coming to the hospital for a long time on this account A severe attack of strangulation of the piles, which had occurred two days before his admission, had finally brought him to the hospital and on admission he was suffering from strangulation of several large piles He was very anæmic and seemed ill and in obvious pain His skin was of a waxy colour, there was considerable puffiness beneath the eyes and slight œdema of both feet The lips and ends of the fingers showed a considerable degree of anæmia. There were a number of large varicose veins on the back of both thighs The patient was very short of breath, apparently from anæmia Examination of the chest showed slight œdema of both lungs The heart was somewhat dilated and there was a well marked hæmic bruit His liver was slightly enlarged Examination of the urine showed no albumin or sugar Examination of the rectum showed a good deal of swelling round the anus and several large prolapsed hæmorrhoids which were thrombosed and of a dark, bluish colour Examination was very difficult as the parts were exceedingly tender He was therefore examined under an anæsthetic and it was then found that not only were the piles thrombosed, but that all the veins of the rectum appeared to be involved for some two inches up the bowel The whole of the plexus of veins in the lower part of the rectum was thrombosed and swollen It was quite impossible to do anything of an operative nature, or even to replace the piles

The patient was sent back to bed and treated with hot fomentations, &c, to try to reduce the swelling Instead of improving the condition became worse. Five days after admission there were signs of sloughing of the rectum and an acute inflammatory swelling began to be evident behind the anus This was incised, and a great deal of foul serum escaped. Two days later a swelling occurred on the left side of the anus and had to be incised The whole of the rectum at this time was gangrenous for some four or five inches The patient had lost all control, he was suffering from almost continuous diarrhœa and was very ill The pulse rate was 110 the temperature fluctuating between 99° and 101° F He also began to complain of severe pain in the abdomen

On the sixteenth day after admission a slough 1¼ inches wide and 4½ inches long which appeared to consist of all the coats of the rectum came away The whole of the buttocks and perineum at this time was œdematous and in a sloughing condition Examination of the urine showed no albumin or pus The patient was very seriously ill During the third week the patient was very tender over the liver and complained frequently of abdominal pain There were a number of large dilated veins on the abdominal wall and extensive œdema of the lower limbs The temperature was still fluctuating, but there were no rigors There was still severe diarrhœa in spite of all treatment Two severe hæmorrhages occurred at the end of the third week, and the patient died two days later, apparently from septicæmia and general weakness

Complete gangrene of all the coats of the rectum as the direct result of thrombosed internal piles seems to us a sufficiently rare condition to be worth recording We are of the opinion that the condition was rendered possible by the secondary anæmia from which the patient was suffering

B. typhosus. Whether they are suffering from active typhoid infection or not can only be determined by repeating the agglutination test at intervals in order to ascertain whether the titre of agglutination shows marked changes or remains practically constant. Such changes are in any case of greater importance in the diagnosis than is the absolute degree of agglutination. They can only be detected with certainty by making use of a standard culture of killed typhoid bacilli and employing the macroscopic method of determination, which is both simpler and more reliable than the microscopic.

A standard culture is readily prepared by the method previously described by one of us (G. D.).

The bacillus (B. typhosus, B. paratyphosus, &c.) is grown for 24 hours at 37° C. in large flasks in a peptone veal bouillon which has been sterilised in the autoclave at 115° C. for not more than 15 minutes. The culture must be made from a young bouillon culture of a typhoid bacillus which has been subcultivated daily in bouillon, preferably throughout several weeks. At the end of 24 hours the flasks are well shaken and 0·1 per cent. of commercial (40 per cent.) formalin is added. They are again shaken and placed in cold store at about 2° C. At intervals on the same day and on subsequent days for four or five days the flasks are again thoroughly shaken in the cold store. After three or four days they will always be found to be absolutely sterile. The bacterial suspension is subsequently diluted with sterile normal saline solution (containing 0·1 per cent. of formalin) to a standard opacity. Should it happen that the suspension is not entirely homogeneous it is filtered through sterile cotton wool and bottled for use in sterile vessels, either sealed or corked.

The standard culture has the following advantages: (1) It is sterile; (2) it is as sensitive to agglutination as the fresh culture, or even more so; (3) it keeps unchanged almost indefinitely if stored in a cool and dark place; and (4) it renders all observations strictly comparable. For the present purpose the agglutination test is made with the patient's serum against B. typhosus, B. paratyphosus (A), and B. paratyphosus (B) simultaneously in parallel experiments.

Method.—Place 15 small narrow sedimentation tubes in a stand in three rows of 5 each. With a proper dropping pipette measure out into a test-tube 54 drops of tap water. Dry out the pipette and with it add 6 drops of the serum to be examined, giving a dilution of 1 in 10. Wash out the pipette carefully.

In tube 1 of each row place 0 drops of tap-water.
" 2 " 5 "
" 3 " 8 "
" 4 " 9 "
" 5 " 10 "

Dry the pipette and use it to add—

To tube 1 in each row 10 drops of the serum dilution (1/10).
" 2 " 5 "
" 3 " 2 "
" 4 " 1 "
" 5 " 0 "

Wash the pipette carefully, and then add to each tube in row 1 15 drops of standard B. typhosus suspension, to each tube in row 2 15 drops of standard B. paratyphosus (B), and to each tube in row 3 15 drops of standard B. paratyphosus (A). Shake each tube thoroughly in order from right to left (beginning with the weakest dilution). Place in the water bath at 55° C.

In tube 1 the serum acts in a dilution is 1 in 25.
" 2 " " 1 in 50.
" 3 " " 1 in 125.
" 4 " " 1 in 250.
Tube 5 without serum is the control against spontaneous agglutination.

Higher dilutions are followed out in a similar manner if the limit of agglutination is not reached within the first series. In inoculated persons who have not had typhoid (or paratyphoid) fever agglutination in a dilution of 1 in 25 justifies a strong suspicion of typhoid (or paratyphoid) infection. But in such a case the test must be repeated in the course of a day or two. Marked agglutination in a dilution of 1 in 50 or more is nearly always diagnostic of active typhoid (or paratyphoid) infection.

The reaction is completed in about two hours if the tubes containing the dilutions are maintained at a temperature of 55° C. in a water bath (50–55° C.). If left at the room temperature 24 hours must be allowed. Obviously the former procedure is to be preferred.

Inoculated persons may give a very high agglutinating titre, as may be seen in Table I. It is therefore necessary to explain briefly the character of the agglutination curve, and the manner in which the results of successive examinations of the serum are to be interpreted.

In the chart the main curve (broken line) shows the course of agglutination in an actual case of typhoid fever. It is indistinguishable in form from the curve obtained by an experimental inoculation with antityphoid vaccine, though its maximum is lower and its decline more rapid than is usual in the inoculated subject. In the same diagram are given observations on three different patients carried out by the method just described. They illustrate some of the chief points which we wish to bring out.

(α T) exhibits the high agglutination titre (1 in 1500) against B. typhosus of the serum of an individual inoculated in September, 1914. It shows no change in three successive observations in the course of six days. During the same period the paratyphoid (B) agglutination (α B) rises rapidly from 1 in 300 to 1 in 700. The agglutination of paratyphoid (A) (α A) is *nil*. Clearly the case is one of paratyphoid (B) infection at an early stage.

(β T) again shows the high and steady typhoid agglutination titre (1 in 1250) of an individual inoculated in August, 1914. Paratyphoid (B) agglutination (β B) during the same period undergoes a striking fall. Paratyphoid (A) agglutination (β A) is *nil*. Again a case of paratyphoid (B) infection.

(γ T) exhibits the steady but now lower typhoid agglutination titre (1 in 250) of an individual inoculated in India as long ago as 1908. His paratyphoid (A) (γ A) and (B) (γ B) agglutination are both *nil*. The patient had neither typhoid fever nor paratyphoid fever.

Apart from the cases of infection occurring in inoculated individuals in which both typhoid and paratyphoid bacilli are agglutinated, other cases occur in the *non-inoculated* where more than one micro-organism is agglutinated by the patient's serum. Here, also, it is necessary to determine the maximum dilution in which each organism is agglutinated, and to follow the agglutination curves in a series of successive observations.

The following statements will afford a sufficient guide in such cases. They are the result of extended general experience, and space does not allow us to present on this occasion the evidence upon which they are based.

1. That bacillus which exhibits the greatest agglutinability (highest agglutination titre) is the infective agent (or the principal infective agent) in the case under examination.

2. If the case is one in which the agglutination of a second micro-organism is due to the presence of *co-agglutinins* the curve of co-agglutination will be found to run parallel to the curve of principal agglutination, but at a lower level.

containing equal quantities of B typhosus, B paratyphosus (B), and B paratyphosus (A) Men already inoculated against B typhosus should also be inoculated against paratyphoid infection, since the antityphoid inoculation offers no appreciable protection against paratyphoid bacilli. The epidemics of typhoid fever reported to be occurring among the belligerents (who are all known to practise antityphoid inoculation) are probably to an important extent epidemics of paratyphoid

2 Unless all cases of "enteric" fever are properly differentiated into typhoid and paratyphoid infection the statistics regarding the value of antityphoid inoculation among our forces in the present war will be most seriously vitiated It is probable that the absence of accurate bacteriological diagnosis in the past explains the fact that the statistical results arrived at in our army have not always been so convincing as would otherwise have been the case

SECTION OF OPHTHALMOLOGY

Cerebral Degeneration associated with Macular Changes—Exhibition of Cases and of a Trench Periscope

A MEETING of this section was held on Feb 3rd, Mr PRIESTLEY SMITH, the President, being in the chair

Dr F E BATTEN and Mr STEPHEN MAYOU contributed a paper on Cerebral Degeneration associated with Macular Changes, and gave a pathological description of a case Dr Batten said that in these cases a curious pigmentation occurred at the macula, and usually also around it, and considerable optic atrophy was also present Several of the examples of the condition which had been under his care died at Darenth Asylum He exhibited the pedigrees of two families In one case the changes in the macula were the last occurrences in the march of degeneration The brains of these patients did not present any macroscopic abnormality, and they had the usual convolutional pattern, as well as the normal weight and relationship to the cerebellum The brain and nervous system were examined by several staining methods There was found to be some degeneration in the medullated fibres, in the cerebellum the myeline was breaking down and degeneration was present in the cells of Purkinje The most profound change was in the Betz cells, instead of the Nissl granules there was a curious accumulation of fine granules around the nucleus In the cerebellum were large granular cells not normally seen and he could not say what their significance was The most marked change was found in the child who had had the disease longest—namely, for three and a half years Th[illegible] ark[illegible] es in the fundus a shrinking of the c[illegible] the Betz cells were too dege[illegible] group was similar to [illegible] family [illegible]iocy, bu[illegible] confined to the retina, but varied enormously in different parts of the fundus The principal change was round the macula region The internal nuclear layers had disappeared altogether, also the rods and cones, and there was some migration of pigment from the retinal pigment cells—The paper was discussed by Mr J H PARSONS and Mr TREACHER COLLINS, and Dr BATTEN and Mr MAYOU replied

Mr A. BERNARD CRIDLAND showed a case of Glass-workers' Cataract in an iron smelter ("puddler"). He brought the case forward to give an opportunity for the discussion of the type of case in ironworkers in relation to industrial diseases, as these men were not included in the schedule Considering the number of hours of exposure to the glare of the molten metal, his surprise was that there were not more cases, especially as these men rarely wore protective goggles He suggested that a more inclusive term should be applied to the cases of cataract so caused such as "ray cataract"—Mr O B GOULDEN said he had a case now under care in a welder, and he thought an investigation would disclose that the condition was more common among ironworkers than was generally believed The man who preceded his patient at the work also lost his sight It was not until quite late that the workers complained, because owing to the dilatation of the pupil they were able to see round the cataract—Dr T M LEGGE (Home Office) asked as to the proportion of ironworkers afflicted with this condition, as it was necessary in considering the scheduling of diseases to proceed tentatively In the case of glass-blowers' cataract there could be no question as to scheduling as he examined the lenses of 513 glass-blowers, and found cortical cataract in 64 in the right eye and 72 in the left—Mr PARSONS said that as secretary of a Royal Society committee on the subject he sent many inquiries to ophthalmic surgeons practising in ironworks districts, and the negative replies he mostly obtained led him to the belief that it was the custom for moulders to wear tinted glasses He asked for further evidence for his committee to continue their investigations—The PRESIDENT suggested the name "furnace-workers' cataract," seeing that furnace work was common to all

Dr E A. COCKAYNE and Dr J ATTLEE showed a case of Amaurotic Family Idiocy in an English child, not Jewish, as was the rule

Mr N BISHOP HARMAN showed a case of Spontaneous Rupture of Cornea in Secondary Glaucoma caused by dislocation of the lens An injury caused total dislocation of one lens into the posterior chamber, where it was loose. The resulting glaucoma was absolute and vision was lost The cornea was anæsthetic and the iris quite retracted and immobile The condition remained so for two years without ulceration of cornea or splitting of Descemet s membrane Three months later, however, without any further accident the cornea was split horizontally and membranes prolapsed the cause having been retrochoroidal hæmorrhage

The PRESIDENT showed a form of Trench Periscope he had just designed At the top of a narrow shaft, 6 feet in length, is fixed at an angle of 45° a plane mirror, about 2½ inches in diameter, and an exact counterpart lower down, the distance from the first being adjustable by pegs and holes Only the top mirror projects above the trench and this can be largely concealed by a piece of earth By looking straight into the lower mirror all movements can be plainly discerned without incurring danger—Lieutenant-Colonel ELLIOTT pointed out how necessary, in order to estimate the distance of the enemy, it was to have the binocular form of periscope.

ROYAL ACADEMY OF MEDICINE IN IRELAND

SECTION OF OBSTETRICS

Fixed Chronic Retroversion of the Uterus—Exhibition of Specimens

A MEETING of this section was held on Jan 15th, Dr [illegible] GIBSON the President being in the chair [illegible] ETHEL SOLOMONS read a paper on Fixed Chronic [illegible] of the Uterus in which he condemned all s[illegible] tments as vaginal douches tampons [illegible] use, firstly, they seldom or never cured, [illegible] the patient a chronic invalid for [illegible]

B typhosus Whether they are suffering from active typhoid infection or not can only be determined by repeating the agglutination test at intervals in order to ascertain whether the titre of agglutination shows marked changes or remains practically constant Such changes are in any case of greater importance in the diagnosis than is the absolute degree of agglutination. They can only be detected with *certainty* by making use of a standard culture of killed typhoid bacilli and employing the macroscopic method of determination, which is both simpler and more reliable than the microscopic

A standard culture is readily prepared by the method previously described by one of us (G D)

The bacillus (B typhosus B paratyphosus, &c.) is grown for 24 hours at 37° C in large flasks in a peptone veal bouillon which has been sterilised in the autoclave at 115° C for not more than 15 minutes The culture must be made from a young bouillon culture of a typhoid bacillus which has been subcultivated daily in bouillon, preferably throughout several weeks At the end of 24 hours the flasks are well shaken and 0 1 per cent of commercial (40 per cent) formalin is added. They are again shaken and placed in cold store at about 2° C At intervals on the same day and on subsequent days for four or five days the flasks are again thoroughly shaken in the cold store After three or four days they will always be found to be absolutely sterile. The bacterial suspension is subsequently diluted with sterile normal saline solution (containing 0 1 per cent of formalin) to a standard opacity Should it happen that the suspension is not entirely homogeneous it is filtered through sterile cotton wool and bottled for use in sterile vessels, either sealed or corked.

The standard culture has the following advantages (1) It is sterile, (2) it is as sensitive to agglutination as the fresh culture or even more so, (3) it keeps unchanged almost indefinitely if stored in a cool and dark place, and (4) it renders all observations strictly comparable For the present purpose the agglutination test is made with the patient's serum against B typhosus, B paratyphosus (A), and B paratyphosus (B) simultaneously in parallel experiments

Method —Place 15 small narrow sedimentation tubes in a stand in three rows of 5 each. With a proper dropping pipette measure out into a test-tube 54 drops of tap-water Dry out the pipette and with it add 6 drops of the serum to be examined giving a dilution of 1 in 10 Wash out the pipette carefully

In tube 1 of each row place 0 drops of tap-water
„ 2 5 „
3 „ 8 „
„ [illegible] 9 „
5 „ 10 „

Dry the pipette and use it to add—

To tube 1 in each row 10 drops of the serum dilution (1 10)
2 „ 5 „ „
3 „ 2 „ „
4 1 „ „
5 „ 0 „ „

Wash the pipette carefully, and then add to each tube in row 1 15 drops of standard B typhosus suspension to each tube in row 2 15 drops of standard B paratyphosus (B) and to each tube in row 3 15 drops of standard B paratyphosus (A) Shake each tube thoroughly in order from right to left (beginning with the weakest dilution) Place in the water bath at 55° C

In tube 1 the serum acts in a dilution is 1 in 25.
2 „ „ „ 1 in 50
3 „ „ 1 in 125.
[illegible] „ 1 in 250

Tube 5 without serum is the control against spontaneous agglutination

Higher dilutions are followed out in a similar manner if the limit of agglutination is not reached within the first series In inoculated persons who have not had typhoid (or paratyphoid) fever agglutination in a dilution of 1 in 25 justifies a strong suspicion of typhoid (or paratyphoid) infection. But in such a case the test must be repeated in the course of a day or two Marked agglutination in a dilution of 1 in 50 or more is nearly always diagnostic of active typhoid (or paratyphoid) infection

The reaction is completed in about two hours if the tubes containing the dilutions are maintained at a temperature of 55° C in a water bath (50–55° C) If left at the room temperature 24 hours must be allowed Obviously the former procedure is to be preferred.

Inoculated persons may give a very high agglutinating titre, as may be seen in Table I It is therefore necessary to explain briefly the character of the agglutination curve, and the manner in which the results of successive examinations of the serum are to be interpreted.

In the chart the main curve (broken line) shows the course of agglutination in an actual case of typhoid fever It is indistinguishable in form from the curve obtained by an experimental inoculation with antityphoid vaccine, though its maximum is lower and its decline more rapid than is usual in the inoculated subject In the same diagram are given observations on three different patients carried out by the method just described They illustrate some of the chief points which we wish to bring out

(αT) exhibits the high agglutination titre (1 in 1500) against B typhosus of the serum of an individual inoculated in September, 1914 It shows no change in three successive observations in the course of six days During the same period the paratyphoid (B) agglutination (αB) rises rapidly from 1 in 300 to 1 in 700 The agglutination of paratyphoid (A) (αA) is *nil* Clearly the case is one of paratyphoid (B) infection at an early stage

(βT) again shows the high and steady typhoid agglutination titre (1 in 1250) of an individual inoculated in August, 1914 Paratyphoid (B) agglutination (βB) during the same period undergoes a striking fall. Paratyphoid (A) agglutination (βA) is *nil*. Again a case of paratyphoid (B) infection.

(γT) exhibits the steady but now lower typhoid agglutination titre (1 in 250) of an individual inoculated in India as long ago as 1908 His paratyphoid (A) (γA) and (B) (γB) agglutination are both *nil* The patient had neither typhoid fever nor paratyphoid fever

Apart from the cases of infection occurring in inoculated individuals in which both typhoid and paratyphoid bacilli are agglutinated, *other* cases occur in the *non inoculated* where more than one micro organism is agglutinated by the patient's serum Here, also, it is necessary to determine the maximum dilution in which each organism is agglutinated, and to follow the agglutination curves in a series of successive observations

The following statements will afford a sufficient guide in such cases They are the result of extended general experience, and space does not allow us to present on this occasion the evidence upon which they are based.

1 That bacillus which exhibits the greatest agglutinability (highest agglutination titre) is the infective agent (or the principal infective agent) in the case under examination

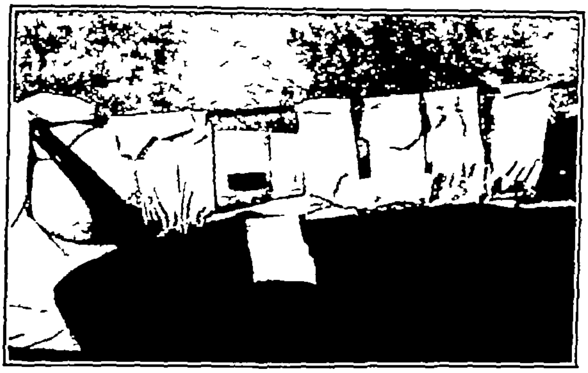
2 If the case is one in which the agglutination of a second micro organism is due to the presence of *co agglutinins* the curve of co agglutination will be found to run parallel to the curve of principal agglutination, but at a lower level.

the strain on either side of the limb to be equal, which it is difficult to ensure if the ends of the pin are fastened to the corresponding ends of the transverse footpiece (Figs 1 and 3)

The distance between the parallel bars ensures the easy application of the dressing, and also enables an operation to be performed while the limb lies stretched in the splint If relaxation is required this can be obtained by reversing the foot screw, and then when extension is required to get the ends in position the screw can again be tightened The essential part of the splint is the screw, and no other method which has been tried produces a like amount of extension with so little discomfort to the patient

This splint has been made by Messrs Allen and Hanbury, of Wigmore street, London, W The cost is somewhat heavy, but I do not think it is out of proportion when the results obtained by the splint are considered In addition, the expenditure is a capital one, and when a number of splints are in hand they can be passed from one case to another, and even sent across the water to accommodate other people in their transit to this country A man once in this splint can be moved with very little discomfort, and constant extension of the limb is maintained in spite of the inevitable movement from bed to stretcher which the wounded have to undertake in the process of removal to the base If one type of splint is to be used for all cases, which can well be done, it is necessary to have the side bars 54 inches long in order to take the limb of a 75 inch man A 66 inch man wants side bars 43 inches long There is no disadvantage in having the long splint except that it sticks over the end of the bed I am, however, having some splints made so that side bars of different lengths can be screwed into the crotch ring This arrangement has the advantage that the splint can be packed flat It would also be possible to have one traction screw attachment for many splints if the transverse foot bar was provided with fastening thumb screws

FIG 4



Shows the patient turned on his side for dressing a posterior wound (represented by a black piece of paper) Note the small cushion under the junction of the side bar and crotch ring The limb is kept from sagging by means of loops of bandage passing round the limb and fastened to the upper side bar They cannot be seen as they are hidden by the slings

A number of these splints have been provided by the British Red Cross Society and are now in use at this hospital

The British Red Cross Hospital Netley

TYPHOID AND PARATYPHOID INFECTION IN RELATION TO ANTITYPHOID INOCULATION,

TOGETHER WITH REMARKS ON THE IMPORTANCE OF THE USE OF PROPHYLACTIC PARATYPHOID INOCULATION[1]

By GEORGES DREYER M A. OXON , M D COPENHAGEN,
PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF OXFORD,
HONORARY CONSULTING PATHOLOGIST TO THE THIRD SOUTHERN GENERAL HOSPITAL

E W AINLEY WALKER, M A , M D OXON ,
LECTURER IN PATHOLOGY IN THE UNIVERSITY OF OXFORD HONORARY ASSISTANT CONSULTING PATHOLOGIST TO THE THIRD SOUTHERN GENERAL HOSPITAL

AND

ALEX G GIBSON, M D OXON , F R C P LOND ,
LECTURER IN MORBID ANATOMY IN THE UNIVERSITY OF OXFORD
CAPTAIN R.A.M C (T), PATHOLOGIST TO THE THIRD SOUTHERN GENERAL HOSPITAL.

AT the present time when the prophylactic value of antityphoid inoculation has been fully recognised by the authorities, but is still vehemently opposed in certain quarters, it may prove not only of interest, but perhaps also of considerable value, to record briefly the results of observations made on patients in the Base Hospital at Oxford

In the light of these observations we wish to emphasise, firstly, the extreme importance of classifying *all* cases returned as cases of "enteric" fever in accordance with the results of detailed bacteriological examination, particularly as regards the precise and careful differentiation between B typhosus and B paratyphosus For if this be not done a large number of cases of paratyphoid fever are likely to be returned as cases of "enteric" The consequence will be that the statistics regarding the protective value of antityphoid inoculation will become seriously vitiated

Secondly, we wish to urge again the importance of making prophylactic inoculations against certain other bacterial infections, some of which have already appeared during the war And on the present occasion we refer particularly to paratyphoid infections, which seem to be occurring with considerable frequency, both in inoculated (antityphoid) and uninoculated individuals The prophylactic paratyphoid inoculation suggested can readily be effected simultaneously with the antityphoid inoculation by using a mixed vaccine, and, so far as the evidence goes, this procedure does not lead to any notable increase in the severity of the reaction produced

The Diagnosis

The agglutination test is the quickest method of diagnosis Blood cultures and cultures *from* the urine and fæces will usually enable the observer to isolate the micro organism where opportunity exists for carrying out repeated examinations But under war conditions the agglutination method is the one on which reliance must be placed Accurate differential diagnosis, however, can only be obtained by *routine* testing of the *serum* of the patient against the three micro organisms B typhosus and B paratyphosus (A) and (B), in parallel series of observations, and by always determining the *maximum* dilution of the serum in which agglutination takes place Individuals who have been inoculated with antityphoid vaccine within a period of some months or even years will give a high agglutination titre against

---

[1] The expenses of this work have been defrayed out of a grant received from the National Medical Research Committee.

(see table) Secondly, it will always show a definite and measurable diminution of titre in the course of a week or two, while in (antityphoid) inoculated individuals whose titre has by lapse of time fallen to a similarly low level no measurable change will be found within the same period.

Prophylactic Paratyphoid Inoculation

Paratyphoid vaccines have been studied by Castellani, Cummins and Cumming, Kabeshima and others This is not the occasion on which to enter into any detailed discussion of their results But the recent work of Kabeshima affords full evidence, both from animal experiment and from extended observations carried out on the personnel of the Imperial Japanese Navy, of the great protective value as well as the innocuous character of the paratyphoid inoculation. Kabeshima used a mixed vaccine containing equal numbers of typhoid, paratyphoid (A), and paratyphoid (B) bacilli About 12,000 men have been inoculated with the mixed vaccine The following table from Kabeshima shows the results recorded in five naval hospitals in Japan during the period 1909–1911 after the introduction of inoculation with the mixed vaccine —

TABLE II —*Kabeshima s Results*

Disease	Total numbers of cases.	Cases in inoculated subjects		Cases in non inoculated subjects	
		Sick	Dead	Sick	Dead
Typhoid	367	68	5	299	40
Paratyphoid (A)...	229	71	2	215	5
Paratyphoid (B)...	447	0	0	447	0

TABLE I.—*Results in Agglutination Tests*

When no agglutination occurred in a dilution of 1 in 25 the record is entered as 0

* In these two cases which are quite recent, it is still uncertain whether the agglutination observed is due to the presence of co-agglutinins or the result of a mixed infection with B paratyphosus (B) and (A)

In view of these results it is unnecessary to adduce further evidence of the fact that by the use of a suitable mixed vaccine adequate protection can be obtained against B typhosus, B paratyphosus (A), and B paratyphosus (B)

As regards the reaction produced, Kabeshima states that when the vaccine used is made up of equal quantities of the three micro organisms concerned, so that the total number of bacilli in the dose does not exceed the usual number present in a dose of antityphoid vaccine, the severity of the reaction (both local and general) is not significantly greater than that following ordinary antityphoid vaccination. Should the question arise as to whether it is better to employ a mixed vaccine of this character or to carry out immunisation against each separate micro organism separately, it may be stated that the former method is preferable Obviously it saves time, and it avoids the frequent repetition of periods of brief temporary disability Moreover, there is ample evidence from observations of Jörgensen, Schroeder, Dreyer, and others that in successive immunisation with these micro organisms the immunity evoked against those organisms which are injected later in the series is less than the immunity obtained when they are mixed together and injected simultaneously, unless a considerable interval is allowed to elapse between the inoculations And this result is independent of the order in which the different micro organisms are employed

Conclusions

1 It is of the utmost importance that our troops should be protected against paratyphoid infection as well as against the B typhosus This can readily be done by the use of a mixed vaccine

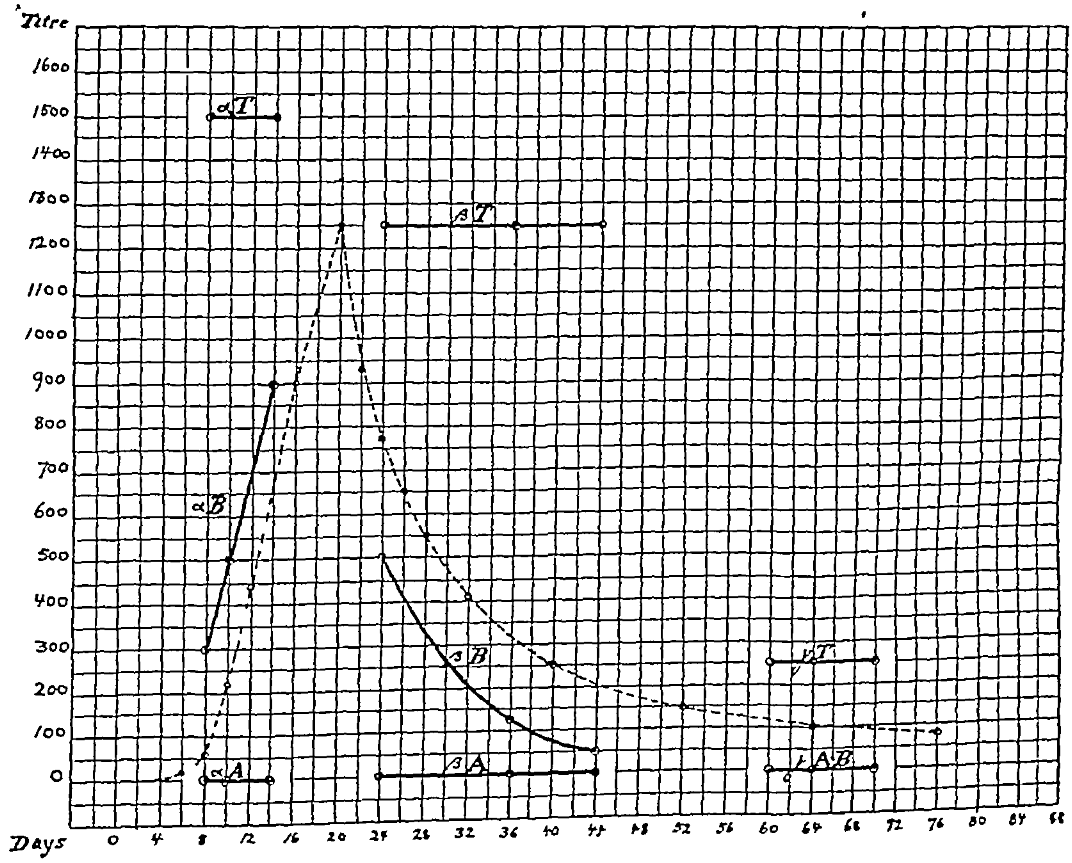
3 *If the case is one of mixed infection with two different organisms their respective curves of agglutination are not parallel, but exhibit totally independent courses, which may even cross one another*

Results

The results of observations carried out on patients in the Base Hospital at Oxford may now briefly be recapitulated. Table I gives all necessary details

Table I contains all those cases out of the large number examined in course of ordinary routine which yielded positive results in agglutination tests It will be seen that of these 20 cases *suffering from continued fever* 8 were diagnosed bacteriologically as typhoid fever and 6 as paratyphoid fever, while the remaining 6 were neither typhoid nor paratyphoid fever

CHART SHOWING COURSE OF AGGLUTINATION



Of the cases of paratyphoid fever one (Case 41) though not inoculated and denying that he had ever had typhoid fever showed a steady typhoid agglutination of 1 in 1250 Up to the present it has not been possible to isolate the B typhosus either from the urine or fæces of this patient. And we do not know yet whether he is a typhoid carrier or has recently passed through a mild unrecognised typhoid infection followed by infection with B paratyphosus (B)

Cases 62 and 68 in the table are of special interest. Both individuals were inoculated against typhoid fever last autumn Both have been in France but never in any other foreign country so far as can be ascertained In each case the serum strongly agglutinates both B paratyphosus (B) and B paratyphosus (A). The cases are either very striking examples of co-agglutination or else as is more probable, they constitute examples of mixed infection From the fæces in each case paratyphoid bacilli (but no typhoid bacilli) have been isolated In each case also two distinct types of paratyphoid bacilli are present. But whether these are merely variants of B paratyphosus (B), or whether the one type is in reality B paratyphosus (A) the other being certainly B paratyphosus (B) has not yet been finally determined The two individuals had never been in contact before the present illness.

The following are the points of chief importance from the table —

1 *No case of typhoid* fever has been found among (antityphoid) inoculated individuals

2 Of *six cases of paratyphoid* infection three occurred in (antityphoid) inoculated subjects Had these cases been returned as cases of "enteric" fever the value of antityphoid inoculation as here exhibited would have been greatly diminished

3 So far as this limited series of cases goes paratyphoid fever has occurred with *equal frequency* among (antityphoid) inoculated and non inoculated individuals This is in agreement with the finding of Kabeshima and others in long series of observations that *antityphoid inoculation affords no appreciable protection against paratyphoid infection*

4 *In no case other than cases of active paratyphoid infection* has the serum of the patient agglutinated B paratyphosus (B) or (A) in a dilution of 1 in 25, even when the titre of typhoid agglutination was very high This statement holds good both for (antityphoid) inoculated individuals and for non inoculated persons suffering from typhoid fever

5 The typhoid agglutination found in *convalescents* from typhoid fever is easily distinguishable from that of inoculated individuals First it is (with very rare exceptions) of *low titre* as contrasted with that of persons recently inoculated whose typhoid agglutination titre remains high

calculus called for immediate operation to save life.—Colonel T H Hendley, I M S, commented upon Mr Bishop Harman's specimens, and cited a case of sympathetic ophthalmia following perforation of one eyeball by a single pellet of shot.—Dr Saunders having been called away, Dr Morton referred to the skiagrams he had made of the cases of early pulmonary tuberculosis in children These were from children in whom the physical signs were either entirely absent or so few and slight as to make it impossible to form any definite opinion on their condition. The X ray appearances in all of them were quite definite, and such as are found in cases proved to be tuberculous Considering the importance of an early diagnosis in indicating the proper treatment at the earliest possible time he urged the advisability of a radiographic examination of the lungs in those children who while presenting no definite signs of any particular disease, were not thriving and enjoying life as others of the same age. With regard to the lung picture before and after sanatorium treatment, here as elsewhere once the bacillus had obtained a footing for a definite period of time a permanent mark was left as evidence of the unwelcome visitation The markings in the lungs after successful treatment followed the same general plan as before, some of the finest 'mottling" might have disappeared but the chief difference might be described as one of diminished contrasts in the picture —Mr Lloyd was not so sure as to how much reliance was to be placed on the X ray findings, and considered that while the radiographic method might be a useful adjunct to other methods of diagnosis it had by no means superseded them At the same time he paid a tribute to the advances made in radiography in recent years

Reviews and Notices of Books.

Pharmacology, Clinical and Experimental

By Dr HANS H MEYER, of Vienna, and Dr R GOTTLIEB of Heidelberg Professors of Pharmacology Authorised translation into English by JOHN TAYLOR HALSEY M D With 65 text illustrations 7 in colour London and Philadelphia J B Lippincott Company 1914 Pp 604 Price 25s net

TAKEN in its widest sense experimental pharmacology is the relation of organisms under chemically changed conditions of environment, and must therefore be regarded as a department of biology The authors treat the subject from two aspects, organotropic—i.e , the action of drugs on function—and etiotropic, their action in disease The pharmacology of the following systems is dealt with in succession—motor nerve endings, central nervous system, sensory nerve endings, the vegetative system, eye, digestion, genital organs, circulation, respiratory organs, the renal function, sweat secretion, metabolism, muscle, blood, temperature, and inflammatory phenomena A special chapter discusses pharmacological effects on the causes of disease and deals with antiseptics, anthelmintics, and antitoxins, acquired immunity, serum therapeutics, the serum treatment of tetanus and diphtheria, and bacteriolysis The last chapter is devoted to the conditions necessary for the action of medicaments, such as solubility, concentration of the drug in the blood the condition of the organism itself to be acted on, antidotes and antagonism, and the various refractive or hypersensitive conditions that are included under the term idiosyncrasy—not for getting anaphylaxis

In the chapter on motor nerve endings curare is very fully dealt with—although it is but little used in medicine—because it gives such a good example of localised action, as well as affords a typical instance of how the action of a drug can be studied As to the pharmacology of the central nervous system, drugs may either increase or diminish its functions, but cannot change these functions qualitatively This section is treated in a lucid, practical, and even masterly manner First those drugs that excite, such as strychnine, and then those that depress and paralyse central nervous functions are discussed, special attention being given to the morphine group Morphine itself occupies a peculiar position owing to its striking and wonderful property of subduing pain, although morphine does not diminish the excitability of the brain and cord to the same extent as such narcotics as alcohol and the chloroform group Special attention is drawn to its action on the respiratory centre Alcohol and inhalation anæsthesia, including ether and chloroform, are next considered Chloral and its cumulative perils are set forth, while trional, veronal, and their allies are discussed and their uses and dangerous effects commented on The well known theory of narcosis of Meyer and Overton is elaborated and the importance of lipoids is emphasised Local anæsthesia is fully treated, most emphasis being laid on cocaine and its allies There is a good coloured plate illustrating the sympathetic nervous system The monograph on the eye in relation to drugs is concise and practical The pharmacology of the digestive tract is treated discreetly in about 60 pages, while 100 are given to the circulatory organs The treatment of the action of digitalis is particularly good

We have instanced only a few points why we cordially commend this treatise to all interested in the progress of pharmacology in relation to scientific medicine Much praise is due to the translator, who is professor of pharmacology, therapeutics, and clinical medicine in Tulane University

---

A History of the Indian Medical Service 1600–1913

By Lieutenant-Colonel D G CRAWFORD, Bengal Medical Service (retired list) London W Thacker and Co 1914 Pp 529 + 535 Price 28s net

IN two handsome octavo volumes there has at length appeared a detailed history of the Indian Medical Service worthy of its subject and fit to rank with any of the regimental histories of the British army hitherto published Of the 45 chapters the first 12 are concerned with the early history of European medicine in India before the formation of the Bengal Medical Service in 1763 The next 15 describe the chief features in the official history of the three separate medical services in Bengal, Madras, and Bombay, and also give a large amount of information on many matters of professional and social interest Chapters XXVIII to XXXIV give in more detail special records of distinguished medical men of the Indian establishment, and in the following 10 chapters are discussed the recent history of the Service and medical matters in India generally

His brother officers, and all concerned with medical practice and education in the East, are indebted to Colonel Crawford for his researches and for the clear manner in which they have been presented to the reader Many curious sidelights are thrown on old time Anglo Indian life which will make the book interesting to the lover of the past, but its main purpose has been to record the gradual evolution of the present homogeneous and uniform service from the small beginnings of the seventeenth century, showing how in the true British way mistakes are made, and order and success

Mr SHEILL showed photographs of a child born with an unusual frænum between the upper maxillary bone and the lip It was not considered of great consequence at the time and was left, but as the child grew older it grew rapidly, and at the time of the development of the teeth he had to cut the frænum, which came level with the tips of the two central incisors He suggested that an epithelial inclusion had been pressed out through the two mesial nasal processes —Mr G P MOORE speaking from the dental surgeon s point of view, said that the condition was better dealt with early, as when it was not treated until after the eruption of the permanent teeth it caused excessive space between the centre incisors and often great irregularity and projection forward of the incisors, which was difficult to cure and very unsightly

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

Marsupialisation of Degenerated and Infected Fibroids —Rupture of Uterus with Fatal Result —Exhibition of Specimens

A MEETING of this society was held in Manchester on Jan 15th Dr J H WILLETT (Liverpool), the President, being in the chair

Dr W E FOTHERGILL (Manchester) mentioned two cases of Large Fibroids he had met with—one in 1899 and the other in 1914—whose adhesions were so dense and so universal that the growths could not be removed In each case the degenerated tumour was scraped away by hand through the abdominal incision until nothing but a thin shell was left The capsule was then stitched to a portion of the abdominal incision In one case the cavity was packed with gauze while in the other double drainage was provided by a long rubber tube, one of whose ends passed down into the vagina while the other opened through the abdominal wound The latter method gave the better result as to rapidity of healing

Dr FOTHERGILL also described the injuries in a case in which the medical attendant performed version and subsequently discovered a complete Rupture of the Uterus The patient was aged 40, and the labour was her tenth at full term She had also had five abortions On admission to hospital the pulse rate was 144 and the patient had lost so much blood that she was gasping The abdomen was opened and its wall above the pubic symphysis was seen to contain extravasated blood The peritoneum was torn from the pubic symphysis in front to a point near the lower pole of the right kidney The bladder was exposed, with the exception of its trigone and the lower part of its left lateral aspect The ureter and the blood vessels on the right side could not be traced through the mass of blood clot and lacerated tissue which occupied the right side of the pelvis and lower abdomen The cæcum and appendix were torn from their bed The uterus was quickly removed and the peritoneum was drawn together A gauze drain was left *in situ for 48 hours* The patient did well for four days but *suppuration occurred* which was confined to the pelvis and she died on the sixth day The records show that this was the seventeenth case of serious rupture of the uterus treated by abdominal hysterectomy at St Mary s Hospitals Manchester the first having been done by Dr Walls in 1905 Of these 17 cases 12 were successful and these 12 women doubtless owed their lives to the removal of the uterus Suture of the rent was not enough in serious cases of uterine rupture.

Dr W K WALLS (Manchester) exhibited the following specimens 1 A Rupture of the Pregnant Uterus through an Old Cæsarean Section Scar removed from a patient aged 30 who had had three previous Cæsarean sections The patient was seven months pregnant when sudden severe abdominal pain commenced, followed soon after by general collapse The abdomen was opened and the peritoneal cavity was found to be full of blood which was *oozing* from the top of the old Cæsarean section scar in the uterus Supravaginal hysterectomy was performed, but the patient died from shock the same evening 2. Cæsarean Section for Accidental Hæmorrhage oozing from the Scar of a previous Cæsarean Section This patient had had one previous Cæsarean section and was within ten days of full term pregnancy for the second time when she commenced with symptoms of accidental hæmorrhage. For this reason Cæsarean section was performed during which the abdominal cavity was found to contain a large quantity of blood This was oozing from the lower part of the old Cæsarean section scar in the uterus which was very broad and thin and would probably soon have opened out along its whole length Supravaginal hysterectomy was performed, and the patient made a good recovery

Dr W FLETCHER SHAW (Manchester) exhibited a specimen of Spontaneous Rupture of Old Cæsarean Section Scar in a Full term Pregnant Uterus This patient had had one previous Cæsarean section and was within a week of full term in her second pregnancy, for which Cæsarean section was again going to be performed, when severe abdominal pain commenced during the night while the patient was in bed. Six hours later she walked to the hospital arriving in a collapsed condition still complaining of severe pain in the middle line of the abdomen from the umbilicus to the pubes and this portion of the abdomen was very tender The pulse was fluttering and uncountable and the temperature subnormal The abdomen was opened and the old uterine Cæsarean scar then found to have completely opened up so that the child was delivered without any enlargement of this wound being required The placenta was on the anterior surface of the uterus and plugged the wound At the time of operation no further bleeding was taking place but the lower part of the abdominal cavity was filled with blood clot. Supravaginal hysterectomy was performed, and the patient made a good recovery

WEST LONDON MEDICO-CHIRURGICAL SOCIETY — A pathological meeting of this society was held on Feb 5th Mr Aslett Baldwin, the President being in the chair The President showed specimens of (1) an Innocent Tumour of the Submaxillary Gland which simulated malignant disease, (2) Stricture of the Transverse Colon, and (3) (with Dr Reginald Morton) radiographs of a Large Ureteral Calculus in a youth aged 15¾ years One of the radiographs was taken after collargol had been injected up the ureter This completely surrounded the calculus and thus verified its position At the operation the ureter above the calculus was found dilated to about the size of the small intestine —Mr McAdam Eccles showed specimens of (1) Gall stones (*a*) causing obstruction (*b*) loose in dilated gall bladder, (*c*) blocking the cystic duct, (2) Vermiform Appendices showing (*a*) mucocele (*b*) papilloma, (*c*) perforation protected by omentum (*d*) colloid carcinoma, (*e*) diverticulum from the side opposite the mesentery —Dr E A Saunders and Dr R K Elworthy showed specimens of two cases of Congenital Disease of the Heart with death from broncho pneumonia.—Dr Elworthy also showed a number of interesting pathological specimens, including one of Aneurysm of the Posterior Communicating Arteries, and also one to illustrate Recurrent Laryngeal Palsy in a child aged 2 years —Dr Saunders and Dr Morton showed radiograms illustrative of Progressive Stages of Early Pulmonary Tuberculosis in Children, also radiograms showing the Lung Picture in Early Pulmonary Tuberculosis before and after sanatorium treatment —Dr H J F Simson showed specimens of Ovarian Cysts Uterine Carcinoma and the Fallopian Tubes from a case of Tuberculous *Peritonitis*— Mr N Bishop Harman showed specimens illustrating (*a*) Spontaneous Rupture of the Cornea in Secondary Glaucoma caused by Dislocation of the Lens, (*b*) Panophthalmitis due to hatpin wound, and (*c*) Sympathetic Ophthalmitis *following sub conjunctival* rupture of the sclerotic —Dr Saunders also showed specimens of the Indian Leech recently introduced by the efforts of Professor A E Shipley to counteract the present shortage of the usual supply from the continent —Commenting on the President s specimen of intestinal obstruction Dr Seymour Taylor pointed out that while obstruction due to malignant disease was placed among the chronic forms rightly in most cases clinical experience showed that malignant obstruction might be acute and cases occurred in which the sufferer was entirely ignorant of the grave disease he had until some urgent condition called for the advice of his medical attendant — The President and Mr F G Lloyd referred to the very interesting series of specimens shown by Mr McAdam Eccles some of them almost unique Particular mention was made of the size to which gall stones and other concretions could reach without giving rise to any serious symptoms, and conversely how frequently a comparatively small students intending to take up chemistry as a profession, particularly in its industrial applications The late Dr Campbell Brown, who was professor of chemistry in the University of Liverpool, possessed an intimate acquaintance with the relations of chemistry to the every day affairs of human life, and at this moment when great opportunities are opening for extending our chemical industries his essays on such subjects as "A French View of German Industries," "What is Technical Education?" "Chemistry as a Profession," "Analytical Chemistry as a Profession," "The Ethics of Chemical Manufacture," come opportunely in this publication His counsels are good and most interesting in view of the "decadence of English chemical industry" (see ill informed writers *passim*)

The Midwives' Companion By FÉLICIE NORTON London J and A. Churchill Pp 101 Price 1*s* net—This book is intended for the use of senior students and midwives In our opinion the author is ill advised to lay so much stress upon asepsis and to say so little about antisepsis, a much better practice for midwives than any attempt to carry out strict asepsis We cannot agree with the recommendation of Schultze's method for the revival of a child suffering from white asphyxia, and we entirely disagree with so called aseptic plugging of the vagina by a midwife for a case of placenta prævia The author might have been more careful in her revision of her proofs

Manual of Training for Jungle and River Warfare London T Werner Laurie Pp 124 Price 3*s* 6*d* net—Major Gordon Casserly, of the Indian Army, has put together in this little book a great deal of useful information From the medical point of view his advice generally is sound and clearly expressed Many native terms are used which might have been translated or explained, and it would have been useful if he had stated what are "the usual precautions" to prevent contamination of a water supply It is not customary to carry an enema syringe in a "pocket case (p 83), and 1 in 100 carbolic acid is not an efficient application to wounds The preventive measures against malaria might have been given more fully On practical matters regarding warfare in the jungle and on river banks the book is most useful It is well illustrated by the author

The Book of Prescriptions By E W LUCAS, F.I.C., F C S Tenth edition London J and A Churchill. 1915 Pp 371 Price 6*s* 6*d* net—The enormous number of drugs brought into use since the last edition of this book was printed would have rendered a fresh issue imperative, even in the absence of a new determining cause in an alteration in the list of official drugs A new British Pharmacopœia, casting out many drugs and absorbing a few fresh articles which have found favour with the medical profession, has led to a revision which is likely to be of great service As a member of the British Pharmacopœia Reference Committee Mr Lucas had already done work which has received special acknowledgment and it may therefore be assumed that he will be a safe guide in many of the pitfalls presented by the new standard The prescriptions should be frequently consulted by beginners who are anxious to adopt the metric system, they are printed in parallel columns with a formula of familiar appearance on the left hand, and with the equivalent in the metric system on the right These object lessons will be very useful to those who wish to move with the times Information relating to many new unofficial remedies has been included, but there is no indication of its unofficial character, it might have been well to mark such paragraphs with an asterisk or other sign The list of synonyms on page 15 appears rather antiquated in attempting to encourage mystification When preparing the next edition with greater leisure it would be well to secure more consistency and to employ the official names and contractions, on the first page it is a surprise to find "hexamethylenetetramine" where the official title "hexamine" should have appeared We meet with Spirit Chlorof and with Sp Chloroformi, with P Saponis and Pulv Saponis, with P Boracis and Pulv Boracis These minor blemishes, however, do not materially detract from the general utility of the book, they are more than counterbalanced by the precision of the text and by the numerous hints to prescribers and dispensers

---

MISCELLANEOUS VOLUMES

NEVER did the British Empire and race stand in more urgent need of the greatest possible excellence in mothercraft than at this present time, when the European nations are engaged in a death struggle The National Association for the Prevention of Infant Mortality and for the Welfare of Infancy has done well in putting forth, under the title of *Mothercraft* (London The National League for Physical Education and Improvement 1915 Pp 244 Price 3*s* net), a course of lectures delivered under its auspices during the winter quarter of last year at the Royal Society of Medicine and Charing Cross Hospital Medical School. These lectures are 16 in number and cover the subject of antenatal preparation of the mother, various forms of infant feeding, the general and special ailments of children, and the establishment and working of infant welfare centres The medical contributors are Dr C W Saleeby, Dr Amand Routh, Dr Harold Waller, Dr F Langmead Dr Eric Pritchard Dr H C Cameron, Dr Ronald Carter, Dr D Forsyth, Lieutenant-Colonel E Roberts M B, Mr Sydney Stephenson, Mr Macleod Yearsley Mr C E Wallis Mrs Florence Willey M D, and Dr F J Allan Marion Fitzgerald writes on How to Visit Homes, and Miss M B Synge adds a chapter on the Clothing of Infants To the end that the book may be widely read by Englishwomen of all classes it would seem desirable that a much cheaper edition should be published.

An interesting series of lectures on *Science and Religion*, delivered by eminent men of science in Browning Hall, London during Science Week, 1914, has recently been published (London W A. Hammond Holborn Hall E C Pp 138 Price 1*s* net) The lectures are as follows Help from the Unseen, by Sir Oliver Lodge F R S, the Supreme Intelligence in and above Nature, by Professor J A. Fleming, F R.S Religion the Crowning Stone of Science, by Professor W B Bottomley, F C S, the Witness of Geology to Revelation, by Professor Edward Hull, F R.S, Science and the Unknown, by Mr John Allen Harker F R.S, the Origin of Life, by Professor G Sims Woodhead, F R.S, Religion and Science their Alleged Incompatibility, by Professor Silvanus Thompson F R S In these essays the reputed incompatibility between the fundamentals of religion and the facts and principles established by science in its various branches is critically investigated by men of established reputation in the scientific world, who put forward reasons for holding that a study of the material aspect of nature, so far from negativing the grounds for a belief in a spiritual substratum and origin entirely supports such a view An introduction describes the aim the speakers and the meetings while Mr J E Stead F R S, adds a rider in the shape of a suggestion that religion must be scientific, by which is meant that its further investigation must be conducted by scientific methods The book contains portraits and brief biographical notes of the speakers and is well worth reading eventually attained by the means of these mistakes As the author quotes from Emerson "They builded better than they knew" We may mention that each chapter has an appropriate poetical heading, which relieves the somewhat dry recital of records and regulations We regret to learn that the time honoured story of the cure of Shah Jehan's daughter by Gabriel Boughton, and the consequent bestowal on him of a grant in favour of the Honourable East India Company, has no foundation The Bengal Medical Service was founded in 1763, on two occasions, in 1766 and 1796, it was divided into two separate services, military and civil, and each time the separation was found to be impracticable, and the two branches were again united Administrative officers of the Army Medical Department were first appointed to India in 1825, and friction appears soon to have arisen between the two services

Colonel Crawford is doubtful as to the suitability of the present system of instruction for I M S officers He considers that Indian diseases would be better studied in India, in the large hospitals of the Presidency towns, which provide an extensive field for research, and are now well equipped with modern appliances The recent history of the Service is treated of in detail as regards scientific, military, civil, and professional matters The author believes that the regimental hospital system will be abolished in the Indian as it was in the British Army It "has outlived its usefulness" A closer relationship between the military and civil branches is desirable How it is to be brought about is not yet apparent Professor Maclean's Christian names were William Campbell, not William Charles, G C B stands for Grand Cross, not Grand Commander, of the Bath (p 210) A list of Fellows of the Royal Society in the Indian Medical Service would be acceptable

Colonel Crawford is to be highly congratulated on the successful accomplishment of his task, while the volumes are extremely well printed and well got up

Flies in Relation to Disease Non Bloodsucking Flies

By G S GRAHAM SMITH, M D Cantab Cambridge University Press 1914 Pp 389 Price 12*s* 6*d* net

WE have already noticed the first edition[1] of this handbook, but the second edition is not merely a reprint with a fresh preface It is an amended and enlarged replica of the original edition, though appearing only a year later Even with such excellent assistance as is offered by the *Zoological Record* it is hard to be sure that a bibliography upon a given zoological subject is exhaustive, and the difficulty obviously increases with the length of the list of titles of works given The author finds 25 pages fairly closely printed necessary for bringing the reader in view of what has been written concerning the muscidæ and other non biting flies It is not therefore surprising to learn that Dr Graham Smith has found that he neglected a few memoirs in the earlier edition These are duly intercalated in their proper places in the present revised bibliography The work to which these papers refer is however, separately dealt with in an appendix together with more recent work which has appeared since the first edition of the book was published This appendix occupies nearly one hundred pages, and is a testimony to the immense output of scientific work nowadays It appears from an inspection of the lists of titles that a large amount of this collected work is from British sources, much also is American, much French, and rather less Italian. The Germans do not bulk so largely

---

Gonorrhœa and its Complications in the Male and Female

By DAVID WATSON, M B, C M Glasg, Surgeon Glasgow Lock Hospital, Dispensary Surgeon for Venereal Diseases Glasgow Royal Infirmary, &c. With 72 illustrations and 12 plates, 9 of which are in colours London Henry Kimpton 1914 Pp 375 Price 15s net

IT is only within recent years that the importance of gonorrhœa has been recognised, even by the medical profession, and still it is regarded as a trivial affection by the general public It is now acknowledged that there is room for discussion whether it is not on the whole a more serious disease than syphilis, when all its numerous complications and sequelæ are borne in mind This book contains one of the best accounts that we have seen of this disease and its treatment, it is comprehensive, it is eminently readable, and above all it is extremely practical The author, while mentioning carefully the various methods which have been employed in treating the different conditions which may occur, explains the grounds on which choice between them should be based With regard to the use of gonococcal vaccine he speaks very definitely, he says that though he is convinced that the vaccine has a specific power to modify the disease, yet he is equally convinced that as yet we have not worked out the data necessary to enable us to use the vaccine with sufficient control over its therapeutic action to justify its indiscriminate employment

The absence of references to original papers should be corrected in future issues

---

LIBRARY TABLE

Text book of Massage and Remedial Gymnastics By L L DESPARD, Member and Examiner, Incorporated Society of Trained Masseuses Second edition London Henry Frowde, Oxford University Press, and Hodder and Stoughton 1914 Pp 413 Price 12*s* 6*d* net—Those who practise massage require to have a knowledge of a certain amount of anatomy, but it is by no means easy to determine what are the exact limits of the anatomy they should be taught In this volume we cannot help thinking that the author has included too much, though perhaps this is an error in the right direction It is surely unnecessary to include in such a work as this details as to the surfaces of the fibula or the origin and insertion of the pectineus muscle At all events, we may rest assured that very few students of massage ever learn such details as these Apart from these structures we have nothing but good to say about this book, the student of massage will find all that he needs in it The large number of illustrations add to the value of the work those representing anatomical structures come from "Cunningham's Anatomy"

Essays and Addresses By the late JAMES CAMPBELL BROWN, D Sc Lond, LL.D Aberd With a portrait and 22 illustrations London J and A Churchill 1914 Pp 208 Price 5s net—We can cordially recommend these essays to the notice of

THE LANCET.

LONDON SATURDAY, FEBRUARY 13, 1915

The Invalid and the Fighting Line

WE called attention recently to a striking manifestation of patriotism shown by subjects of aortic insufficiency who, while quite aware of the nature of their disability, had nevertheless been found in the fighting line of the French army. A recent report to the Academie de Medecine has shown that this display of heroism has been widespread, incidentally proving that compensation in quite serious cardiac lesions is for a time often very complete. The situation, however, that may arise from the successful attempt upon the part of a physically damaged man to enrol himself in the army as sound may be so serious that while we admire we regret such exploits. And the French army is not singular in providing examples. The experience of the medical men who passed recruits for enlistment in our rapidly created army was, as is known, satisfactory on the whole; it entirely contradicted the more gloomy prognostications of the untiring prophets of our physical decay as a *nation*, while the summary inspection led to the immediate remedy in many cases of minor evils which in all probability would have otherwise gone unattended, inasmuch as their subjects had finished their school careers before the national system of inspection was in effective order. The good health now maintained in our army is a proof that in physique and stamina there has not been the widespread deterioration which in many magazine articles we were asked to face, while on the other hand the capacity shown by masses of men drawn from every class, varying in age by 20 years, and in many cases not distinguished by external signs of rude health or muscular vigour, to endure the shocks of actual war as well as the strenuous labour of military training, has been surprising. There has, of course, been from time to time sickness in different camps, but by treatment and prevention, by the coöperation of the medical and sanitary branches with military chiefs who understood the importance of hygiene, the health of our troops has been conserved in a wonderful manner. But undoubtedly a certain number of unfit men were accepted. The work of the recruiting medical officers in the *first days* of stress was done at full speed, and we have all heard of individual cases of recruits whose disabilities for a military life were manifested very quickly. And it was quite well known that the enrolment of some of these men was not due so much to the hurry of the recruiting procedure as to that very spirit of heroism which has been so markedly displayed by cardiac subjects in France.

At the meeting of the Academie de Medecine of Paris M. Ch. FIESSINGER reported some truly remarkable cases in which the subjects of other forms of heart disease showed as much staying power as those suffering from aortic insufficiency. The declaration of war caused, said M. FIESSINGER, the national energies to manifest themselves in an "élan incomparable," and under the stimulus failing organs worked better for a time. Those who had good reason to remain at home ignored medical advice and went to the frontier like the others. M. FIESSINGER referred to 12 cases, in 6 of which the patients were retired officers. The remaining 6 were officers in the army, who would no longer incur the shame of being considered "infirmes" and followed their comrades. The diseases present in these 12 cases were as follows: in 5 affections of the myocardium (myocarditis or renal heart), paroxysmal tachycardia in 1, and valvular disease in 6 (3 cases of mitral regurgitation, 1 of *mitral* obstruction, and 2 of aortic insufficiency). The treatment usually followed was administration of 1/10th of a milligramme of crystalline digitalin for two or three consecutive days as a prophylactic when the heart was not failing, and the same dose for 10 consecutive days with intervals of four days when there were signs of myocardial failure. As might have been foreseen, the subjects of valvular disease stood the campaign better than those who had myocardial disease. An infantry captain and two lieutenants who had well-compensated mitral disease were able with the aid of digitalin to endure the fatigue of the life of combat. An officer, aged 23 years, who had retired from the army in consequence of aortic insufficiency, rejoined and took part in the battle of the Marne, but forgetting to take his digitalis his heart dilated. He rested for a fortnight and then returned, but was discharged in spite of his protestations. An officer, aged 26 years, who had retired from the service in consequence of aortic insufficiency, re-engaged as an aviator. In the middle of August he fell with his machine from a height of 20 metres. His shoulder was dislocated and he was covered with bruises. He came to M. FIESSINGER for examination of his heart. He was doing well, and he soon resumed aerial work. A major in the medical corps suffering from mitral obstruction remained alone on the field with more than 700 wounded after the disaster in Lorraine to the 15th Corps. He was taken prisoner and afterwards exchanged for a German army surgeon taken prisoner by the French. He rejoined his corps and passed many days and nights at the *front* until increasing dyspnœa vanquished him. To M. FIESSINGER's advice to take a fortnight's rest he replied that it was impossible. He kept his bed for 48 hours and then rejoined. Two officers—one an "intendant general" in the Army Service Corps, on whom depended the supplies of food of 350,000, the other a major in the veterinary service, who slept on straw for several weeks at a time, treating men more often than horses, and giving numerous injections of

The Balkan Cockpit, by W H CRAWFURD PRICE (London T Werner Laurie Pp 369 Price 10*s* 6*d* net), is a pleasantly written chronicle of the war of 1912–13 between the Balkan Alliance (Bulgaria, Greece Montenegro, Serbia) and Turkey, together with the ensuing war between the Allies—namely, Bulgaria against the other three The downfall of Turkey in the first instance and the defeat of Bulgaria in the second are still bearing fruit in the present general European conflict From a medical point of view the most interesting portion of the book is the account which Mr Price gives of the admirable paper organisation of the Turkish military medical force and its hopeless breakdown in action Further, although the Turkish Red Crescent organisation worked well the authorities thereof refused to lend a helping hand to their military brethren, whose hospitals were lamentably understaffed and were without food, medical comforts, bandages or medicines

Miss ETHEL C HARGROVE went to Portugal on the invitation of the Sociedad Propaganda de Portugal as a member of the British International Association of Journalists, and her book, *Progressive Portugal* (London T Werner Laurie 1914 Pp 276 Price 6*s* net), is a brightly written, if superficial, account of what she saw and did there Portugal, which has been Britain's ally from the time of the Crusades, is a country with a most interesting history Its climate, architecture, and vegetation are all fascinating and but little known to the majority of British travellers The recent change of government has apparently been of an awakening nature, and Miss Hargrove points out that the Republic took early steps to reorganise the public institutions, especially the hospitals, which are now being modernised all round. The book is supplied with a map and with numerous illustrations, but we have also noticed an unduly large number of misprints.

Of books for students of the résumé class there are two kinds—those that should be unhesitatingly condemned for inherent defects and those that are not dangerous unless improperly used, and may even serve a useful purpose if used merely to systematise knowledge To the latter class belongs *Aids to Pathology*, by Dr HARRY CAMPBELL (London Baillière, Tindall, and Cox 1915 Pp 228 Price 3*s* net, in cloth 3*s* 6*d* net) The third edition of this book contains much additional matter on immunity A chapter on diseases of the heart has been added, and there is considerable amplification in other directions

JOURNALS

British Dental Journal —The first January issue of this journal contains a paper by Mr W Hern on Oral Hygiene and Prophylaxis After recounting the various conditions giving rise to gingivitis Mr Hern discusses the most efficient means of keeping the mouth in a state of cleanliness He seems to think that reliance can be placed upon the use of the tooth brush, and suggests patterns of brushes to be used as well as the methods for brushing the teeth He discusses briefly the value of tooth powders, and incidentally does not place much reliance upon the use of antiseptic washes The discussion on the paper is printed, and many of the speakers obviously thought that the question of oral hygiene and prophylaxis should be approached from rather a broader point of view than that suggested by Mr Hern—viz, on the broad lines of dietetics and efficient mastication —Mr W H Gilmour reports an interesting case of fractured teeth from a bullet, the bullet having indentations on both upper and lower surfaces —Mr Arthur Underwood contributes a very interesting letter on the question of the scarcity of dental practitioners and thinks that the cause rests in the unsatisfactory condition of dental legislation —The issue for Jan 15th contains an article by F W Broderick on The Relation between Calcium Metabolism and Dental Diseases The author discusses the manner in which calcium is found in the body and describes how the calcium balance is maintained He considers that caries is the result of a deficient calcium output which reduces the alkalinity of the saliva while he regards periodontal disease as due to calcium saturation the excess salts being deposited around the necks of the teeth and acting as mechanical irritants press the gum margins away and lay them open to infection There is a reprint of a lecture by Mr Howard Mummery on Calcification, also two letters dealing with the question of shortage of qualified dentists

New Inventions.

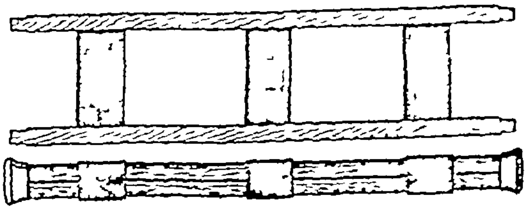
VENTILATED ELASTIC STOCKINGS FOR VARICOSE VEINS

THE medical profession will, I think, be glad to have their attention called to a ventilated stocking which I have recently been employing in cases of varicose veins associated with eczema. In these cases patients often complain bitterly of the almost intolerable itching provoked by the heat inseparable from the use of stockings of solid elastic The substitution of perforated bandages is but a partial remedy for the drawback the necessary overlapping of the folds of the bandage neutralising to some extent the effect of the perforation The intense irritation suffered in an exceptionally severe case of mine prompted me to consult Messrs Maw Son, and Sons as to the practicability of constructing an elastic stocking on the principle of cellular clothing The attempt was made, and made successfully, for I have tried the stocking in a number of appropriate cases and have found that it admirably fulfils the desired purpose of affording support without heat The stocking composed of finely meshed silk and elastic, supports the distended veins not less effectually than does a stocking of solid elastic while permitting free ventilation For obvious reasons in cases in which there is discharge it must not be applied until the exudation has ceased Where economy is an important consideration cotton can be substituted for silk and, whether made of the one material or of the other, the stocking can be employed with advantage in cases of uncomplicated varicose veins as well as in those in which there is associated eczema

Harley street W MALCOLM MORRIS, F R C S Edin

THE "STICK" LEG REST

THIS ingenious little invention consists of a very stout stick split in halves the halves being joined by bands of webbing as shown in the picture The halves closed and secured by a thick rubber cap on each end make a stout walking stick When the halves are separated the stick becomes a leg rest of a very comfortable sort in any position, each half is converted into an adjustable splint the leg resting comfortably on the webbing The length of the stick is 33 inches so that as a rest the apparatus just fits across the seat of a railway train The removing the caps to open up the stick is simple, and the caps are very substantial so that they may not be worn out by use as ferrules The price of the stick leg rest is 4*s* 6*d* and all communications should be made to Mr George Marshall Seymour Works, Seymour place Bryanston square, London, W



BELGIAN REFUGEES UNDER THE INSURANCE ACTS —A circular of the Local Government Board addressed to local refugee committees has given explanations as to the position of Belgian refugees towards insurance when they obtain employment in this country Employers have to pay the same contributions whether they employ their countrymen or Belgians The refugee in certain circumstances may claim exemption, as may the British subject The Belgian if insured must obtain a card and either join an Approved Society or remain outside as he may prefer His benefits from the society will be such as it is in a position to give in return for his contributions He will in fact be in the position of an ordinary foreigner By joining an Approved Society he will usually become entitled to medical and sanatorium benefits at once but will not be in the same position as a British subject with regard to other benefits stimulation. This stimulation is assumed to be due by some observers to an increase in the oxidising powers of the oxidising enzymes, so that destruction of the hindering compounds can be accomplished as quickly as they are formed, growth thus continuing more rapidly. Manganese possibly intervenes as a catalytic agent in the material changes of which plants are the seat, and the metal thus participates in an indirect manner in the building up of the tissues and in the production of organic matter. And this great accelerated synthetic result is the outcome of an application of a solution containing 1 part of the salt in 100 million parts.

In considering the experimental work that has so far been done on the subject of poisoning and stimulation Dr BRENCHLEY concludes that it is not true to maintain the hypothesis which some have done that all inorganic plant poisons act as stimulants when they are present in very small quantities, for while some poisons do increase plant growth under such conditions others fail to do so in any circumstances. It is more probable that some inorganic poisons act as stimulants when present in small amounts, the stimulating concentrations varying both with the poisons used and the plants on which they act. The researches on this subject have attracted considerable attention, and their development will be watched with the keenest interest. The particular work on agricultural applications apart, it is obvious that as these investigations are pursued they may help to clear up much of the obscurity which surrounds the remarkable action of small entities in the human body.

Annotations.

"Ne quid nimis."

FAMILY RESEMBLANCES

HAD the "Slingsby Case" been tried in less stirring times it certainly would have attracted a greater share of public attention, particularly from those who are interested in the inheritance of physical characters. Mr Justice Bargrave Deane recognised a close degree of resemblance between the boy defendant and his father, Mr Charles Slingsby, particularly in the case of the lower jaw, Sir George Frampton detected a likeness between the ears of the boy and his mother. On the day on which the learned judge gave his judgment a well known anthropologist, an anatomist famous for his accuracy, descended in a lift with two men and a boy, all three of whom stared stolidly at the advertisements on the wall. One of the men was short and dark, the other fair and of medium height. The expert at once assigned the little boy as son to the fair man from their close resemblance. As the lift gates swung open the boy took the dark man by the hand, called him 'dad,' while the fair man went his own separate way. In telling us his experience he adds: "Another case of misidentification came under my notice on the evening of the same day. An intelligent and experienced lady called on a friend who took her up to the nursery to see the latest born. The visitor found two nurses and two babies, and exclaimed, 'Well, I need not ask which it is, this one is your image.' She then selected the wrong child." From such cases one must conclude that general resemblances may prove misleading. But it is otherwise with particular features, such as the Hapsburg lip. Medical men are well aware of such features, a nose, an eye, or an ear may have such a pronounced shape that a family identification may be made with certainty. Individuals with pronounced features are in the minority. There is no question that such features may be and are inherited. In many instances the characteristic form is not apparent in the young, it becomes fully developed after adolescence, and this is especially true in the case of the nose, and is also the case with the lower jaw. The boy defendant is 4 years of age, in the next 16 years his jaw will be remodelled over and over again to make room for the permanent molar teeth, the teeth which will replace his milk set and to fit the growth of the upper jaw, it would be at maturity we should expect a real, not an apparent, resemblance of the paternal form of jaw to appear. The ear offers a more certain means of identification of likeness, but very few men have studied this complex structure so closely as to be in a position to offer an expert opinion as to degree of likeness. In the photographs which have been published of the parties in the Slingsby case an expert has little difficulty in recognising what was apparently regarded as a striking feature of the "Slingsby" ear. The resemblance lies in the degree to which the hinder border of the ear is folded over so as to form a welt. It is well known that the folding of the ear margin is a result of retrogression, the more the border is folded over the greater is the degree of developmental retrogression. There is no folding of the border of the ear in the more primitive apes, in some of the higher apes, especially in the orang, there is a high degree of infolding, for the ear of the orang is more retrograde than that of most human races. A considerable degree of infolding of the ear is so common that an anthropologist would give it only a slight value in working out resemblances. Sir George Frampton's method of observation we do not know, but we must admit that sculptors have certainly a right to express an opinion. It was Thomas Woolner who drew Darwin's attention to the presence of a nodule on the welt of the human ear which the great evolutionist recognised as a remnant of the ancient pointed tip. That all parties concerned in the Slingsby case should show a trace of the ancient tip is not a matter for surprise, the ear is exceptional which shows no sign of this ancient mark.

MEDICAL RECIPROCITY WITH BELGIUM

THE Executive Committee of the General Medical Council at its last meeting on Jan. 22nd had before it the recent Order in Council extending Part II of the Medical Act of 1886 to the kingdom of Belgium.[1] The committee considered evidence submitted to it by Belgian professors, graduates, and others with regard to the course of study and examinations which candidates had to undergo in order to obtain the degree of Doctor of Medicine in the universities of Belgium and the legal authorisation antitetanic serum—suffered from renal heart with tachycardia and cardiac gallop Yet they have been through the campaign for over three months and are still well Such devotion, said M Fiessinger, is a magnificent page in the annals of France

---

[1] THE LANCET, Jan. 16th, 1915, p. 143.

We have every sympathy with the urgent desire of him who, despite some physical condition that might prove a bar, desires to enlist, but a good physical standard of all is an absolute necessity for the common safety of an army Modern conditions of war have made that standard much more elastic, place has been found in the ranks for the small man, for the man who is too tall (theoretically) for his weight, for the man who wears glasses, and for much other first class material that formerly could not be employed, but there should be no leniency shown towards the applications of those whose infirmities might prove a source of danger to others The recruit who deliberately conceals his epileptic history is not serving his country really, he cannot remain in the ranks while subject to such a disease, and his detection may be the sequel to a tragedy It is possible to condone the case of the healthy middle aged man who confuses his chest measurement with his age in entering himself as 37, many victims of cardiac disease do not themselves know their plight, and if they are admitted to the army the fault is not theirs, but those who conceal conditions difficult to diagnose which, if known, would rightly debar them from military service, make an error—even though a gallant one, for they might break down at a moment when upon their efficiency depended the safety of many comrades

The Physiology of the Minute Quantity

A good many years ago chemists talked of catalytic action, and the expression then was, as most must confess, merely a convenient expression What it really meant was that a chemical reaction between two agents was highly stimulated by a third, albeit this third body was infinitesimal in quantity and unchanged We now possess a quite large number of examples in which catalysis plays an important and even essential part not only in inorganic chemical changes but in life processes also Taking an example of pure chemistry first, the union of hydrogen and oxygen in practically unlimited quantity may be effected, as is well known, by mere traces of colloidal platinum, while without its intervention the elements might remain for ever apart The common and striking feature of catalysis is that the quantity of the catalyst is very small compared with the quantities of the main reacting substances, and this feature is also illustrated in the action of the organic catalyst, the enzyme The enzymes, in fact, bear a close analogy to the ordinary inorganic catalysts Thus the enzyme invertase is capable of inverting 100,000 times its own weight of cane sugar, and its activity is practically unimpaired through the process, particularly when the ultimate product is removed as fast as it appears

A more recent development of catalysis has been made in plant physiology, which promises to be of the utmost importance to agriculture, while the circumstances in which we live necessarily turn the attention of thoughtful people to the productivity of the soil It has been found that minute traces of certain mineral bodies may promote or hinder healthy plant growth, just as the presence of a minute quantity of iodine in the thyroid gland determines its activity In a suggestive monograph forming one of the agricultural series issued from the Cambridge University Press,[1] Dr Winifred Brenchley records the results of some experiments made at Rothamsted experimental station on the influence of certain metallic compounds on vegetable growth The trials are by no means complete, but they indicate that a very interesting and entirely unexplored field is being approached The prospect at any rate is opened up of the possibility of utilising certain stimulating compounds as artificial manures, and Dr Brenchley points out that as only small traces are beneficial, larger amounts being poisonous to the plant, it is obvious that only small quantities would be needed Again, the compounds are not usually very expensive and thus a considerable increase of crop for a relatively small outlay might be anticipated if no complicating factors intervened In this interesting investigation a very limited number of plant poisons were investigated, but sufficient evidence was adduced to show that even these few differ considerably in their action upon plant life While, to quote some examples, certain compounds of copper, zinc, and arsenic are exceedingly poisonous, compounds of manganese and boron are far less deleterious, so that a plant can withstand the presence of far more of the latter substances than of the former The tested compounds of copper, zinc, and arsenic do not seem to stimulate growth, even when they are applied in the smallest quantities, whereas very dilute solutions of manganese and boron compounds decidedly increase growth A differentiation, however is shown even in this stimulative action, for while manganese is the more effective in stimulating barley, boric acid is far more potent for peas, the shoots being particularly improved The minute quantity of manganese sufficient to produce stimulation is very remarkable, since 1 part of the sulphate in 100 millions was found to exercise a beneficial action The yields were increased in some experiments by as much as 41 per cent in the case of spinach, 19 4 per cent in the case of peas 13 9 per cent in the case of flax, and 5 3 per cent. in the case of barley In some investigations carried out with rice in Japan the harvest of grains was increased by one third owing to careful manganese

[1] Inorganic Plant Poisons and Stimulants By Winifred E Brenchley, D.Sc F.L.S Cambridge University Press

REMUNERATION ON THE PANELS

It is fairly evident that if there had been no war there would have been a considerable amount of disappointment and resentment felt by medical men on the panels of many districts owing to their receiving as their remuneration for 1914 less than they had reason to expect, and owing to their only receiving the balances acknowledged to be due by the committees after appreciable delay In the present circumstances the war is responsible for an increase in the difficulty of the position owing to the number of insured persons who have enlisted There are no contributions made by them or on their behalf by their employers, and owing to the drain upon clerical staffs everywhere arrears of work have accumulated, with general dislocation of business It is too early to say what may be done in the future in order to relieve the situation, but it seems very doubtful whether committees can be compelled to find money and make payments where the ordinary working of the Insurance Act does not provide it At the same time the hardship to the medical profession and to the druggists must be great when payments which they have had every right to expect are postponed or withheld The medical practitioners have had to arrange the organisation of their professional work to meet the demands of their insured patients upon their time and attention, and the druggists have had to meet anticipated requirements by laying in stocks of drugs which have to be paid for Both have to contemplate the return of many insured persons serving in the army with wounds or with impaired health, and a general alteration of the probabilities with regard to their need for medical care For the rectification of some part at any rate of legitimate causes of complaint it may be necessary to wait until the war is over and legislation can proceed upon more normal lines than now At present it may be urged on behalf of the medical men affected that they are entitled to demand payment upon all patients on their lists until they have been notified as provided for by Regulation 29, and that if the financial provisions of the Insurance Act do not meet the needs created by war, legislation should supply the deficit

THE ADMINISTRATION OF THE PHARMACY ACTS

The annual report of the Registrar of the Pharmaceutical Society, which was presented to the council at the February meeting shows that as regards membership the steady progress which has been revealed by these reports during the last ten years or more is well maintained The number of members is now well over 8000, which is about half the number of registered persons, the majority of the non members no doubt consist of qualified chemists who are not yet in business on their own account There is also an increase in the number of names on the Pharmaceutical Register, and although this increase is only slight it is satisfactory to know there is an increase, while the fact that there has been a considerable accession to the ranks of the registered students is very promising From the general point of view the most interesting part of the report is that which deals with the administration of the penal clauses of the Pharmacy Acts The number of cases of alleged infringement that require investigation is still large, but smaller than it was during the previous year During 1914 1113 cases were investigated, and in 239 cases proceedings were instituted, and the council was successful in all but one or two The list of offenders is headed by unqualified drug store proprietors, of whom 93 were proceeded against, the offence generally being that of keeping open shop for the sale of poisons Among the persons by whom penalties were paid there were also a number of qualified pharmacists who had committed one or other of the irregularities which are offences under the law regulating the sale of poisons The list of offenders also includes unqualified assistants in drug stores, unqualified managers and assistants to chemists, executors to chemists, limited companies trading as chemists and druggists, unqualified directors of limited companies, grocers, herbalists, general storekeepers, and one ironmonger, one seedsman, one oilman, one manure agent, and one unqualified assistant to a doctor It is evident from the variety of the occupations of the persons proceeded against that the task of preventing the irregular sale of poisons is no light one In five cases of alleged infringement of the Pharmacy Acts which had been reported it was found upon analysis that the poison asked for had been omitted from the articles purchased, and proceedings could not, therefore, be taken under these Acts, but pursuing the policy decided upon some years ago the council proceeded in two of these cases under the Merchandise Marks Acts, and the defendants were convicted for selling goods to which a false trade description was applied.

THE STREPTOCOCCUS VIRIDANS IN INFECTIONS OF THE UPPER RESPIRATORY TRACT

An interesting paper is published in the *Archives of Internal Medicine* for Jan. 15th by Dr Russell L Cecil, of New York He adopts the classification of streptococci put forward by Schottmueller, based on the appearances of the colonies on blood agar—namely, S hæmolyticus (longus, pyogenes), S viridans (mitior), and S mucosus Dr Cecil states it to have been found by many investigators that clinically the S hæmolyticus produces suppurative or phlegmonous inflammations, while the S viridans usually leads to catarrhal processes His own work has been specially devoted to determining the part played by the latter organism in infections of the upper respiratory tract From the study of 89 cases of such infections he found the S viridans to be the predominant organism in 50 cases, or 56 2 per cent In general these infections were characterised by a mild course and a tendency to chronicity with frequent recurrences, which he attributes to the short duration of the acquired immunity These infections of the upper respiratory tract due to S viridans, especially those of the tonsils, sinuses, and the tooth sockets, are frequently associated with endocarditis and arthritis, and he is of opinion that there is a good deal of evidence that the latter conditions are secondary to the former He has found autogenous vaccines to be of considerable value in cases where the structural changes are not too advanced, but he takes care to point out that in cases of bronchitis with emphysema or bronchiectasis, old sinus infections with thickened walls, and advanced pyorrhœa with retraction of the gums, vaccines can bestow only limited benefits. He believes that vaccines are more especially to practise in that country The committee was satisfied with the evidence produced, and resolved as follows —

> That so long as the Order in Council of Jan 7th, 1915, remains in force any person who produces evidence satisfactory to the Registrar that he has obtained the degree of Doctor of Medicine in the Belgian universities of Brussels, Ghent, Liége, and Louvain, and is legally authorised to practise medicine, surgery, and midwifery in Belgium, and who satisfies the Registrar as to the other particulars specified in Section 12 of Part II of the Medical Act, 1886, shall be entitled to be registered in the Foreign List of the Medical Register

Further communications received by the Registrar of the General Medical Council, through the clerk of the Privy Council and His Majesty's Minister at Havre, from the Belgian Government, afford official confirmation of the evidence placed before the Executive Committee as to the education and examinations on which medical qualifications are conferred by Belgian universities and colleges The Acting Minister of the Interior, in the course of his note to Sir Francis Villiers, used the following appreciative words "Veuillez croire, Excellence, que le Gouvernement Belge est très sensible a cette nouvelle marque de la sympathie de l'Angleterre et qu'il en remercie vivement les autorites de votre pays" In the absence of complete information on Jan. 22nd, the question of the recognition of Belgian dental diplomas was held over until the next meeting of the Executive Committee

THE HUMAN STOMACH AND THE CANALIS GASTRICUS

It has been commonly supposed that fluids and solids on being swallowed must necessarily be mixed up in the stomach, but there is now much important evidence to show that such a view must be revised It is held that fluids can be swallowed, in fact usually are swallowed, and yet not mix with other ingesta within the lumen of the stomach, they pass on, by the aid of a special arrangement to be immediately noted, direct from the cardiac orifice to the pylorus Comparative anatomy has shown that such an arrangement holds good for ruminants, and at a later time it was discovered that carnivora possess the same faculty, despite the fact that in them the stomach is a single chamber Recently Dr F T Lewis has called attention to a canal along the lesser curvature of the human fœtal stomach, he has called it the "canalis gastricus' He says ' it suggests a continuation of the œsophagus and may become a tube during its physiological activity, by the approximation of its lips" Some recent radiographic and anatomical researches by Dr Geoffrey Jefferson in the *Journal of Anatomy and Physiology* (1915, vol xlix, p 165) give further strong support to the likelihood of some action such as this persisting in adults and realising in this way a selective course to the pylorus for fluids Screen examinations of 22 normal people after being given a mixture of bismuth oxychloride and milk of the consistency of thin cream showed that in 18 instances the fluid was confined to the lesser curvature, in the other 4 cases it spread rapidly over the sides of the stomach, but these stomachs were atonic That such a course does not merely represent the shortest path gravity would demand is shown by the holding up of some portion just below the cardiac orifice Nor does Dr Jefferson agree wholly with Dr Hertz that the normal empty stomach is contracted down like a piece of small intestine, the localised stream being accounted for in this way That the stomach really makes a coördinated effort to direct the fluid into a channel at its lesser curvature is thus suggested by X rays Finally, there must be recognised the active part played by the oblique muscle of the stomach in accomplishing this local canalisation It is probably by the contraction of its upper fibres that the bismuth, as seen by the screen, was so constantly held up below the cardiac orifice This sheath of muscle, in fact, is of more importance than was supposed, and its action aids in forming this functional "canalis gastricus" Further proof of the specialisation of the lesser curvature of the pars cardiaca for some function other than that of slowly pressing the food out into the outer pyloric part is shown by the marked difference in the action of the muscle along the lesser curvature as seen by X rays, the change occurring at the incisura angularis The whole diameter of the pars pylorica takes part in active peristaltic waves coursing towards the pylorus It is, however, very rare to see any indentation of the lesser curvature in the pars cardiaca There thus seems to be a fundamental functional difference between the two parts, which gains its best explanation from the facts above discussed

SMALL-POX, VARICELLA, AND "ALASTRIM"

The discussion at the Royal Society of Medicine[1] arising out of a paper read by Dr W G Armstrong on the subject of the epidemic of small pox at Sydney in 1913 was in many respects interesting and suggestive The peculiar feature of the epidemic in question was the mildness of the symptoms, although the population affected was largely unvaccinated Thus, in many instances there were but few cutaneous lesions, while in a patient who presented a severe confluent eruption on the face and extremities the constitutional disturbance was so slight that the man's complaint was only of the insufficient food given him and of the soreness of his feet if he tried to stand on them There was only one death among over 1000 cases of the disease Coincidently with this epidemic of small pox there was an increase in the prevalence of varicella, but the behaviour of the two diseases with regard to vaccination negatived any possibility of the epidemic being of hybrid character Epidemics of specially mild small pox have been observed in many parts of the world and have received different names, such as milk pox, Cuban itch, Spanish measles, and "alastrim , and doubt has prevailed as to the identity of these mild forms with true variola Dr C J Martin quoted a report by Ribas, of São Paulo, who upheld the diversity of the local disease known in Brazil as "alastrim ' from small pox owing to its low mortality, its trivial degree of constitutional disturbance, the absence of the characteristic smell and the possibility of successfully vaccinating patients within a short period after the attack On the whole, the evidence is in favour of regarding all these conditions as mild variola, and the success of Dr J Burton Cleland and Dr E W Ferguson in inoculating calves with material derived from patients in the Sydney epidemic affords powerful support to this view Dr Martin, however suggests that the three diseases—small pox, chicken pox and "alastrim'—are of common parentage but have become so far differentiated as to breed true at the present time

THE CORNWALL COUNTY ANALYST AND PRESERVATIVES IN FOOD —At the last meeting of the General Purposes Committee of the Cornwall County Council the county analyst (Dr Kitts) reported that during the past four years slightly over 1 per cent of the milks had been treated with a preservative and 5 per cent of the butter samples In margarine 95 per cent of the specimens examined had contained a boric compound in small quantities Dr Kitts stated that when preservatives had been used in other articles of diet the user had sometimes not even known the name of the powder he had used to say nothing of its possible physiological effects, the vendors persuaded the users that the substances were perfectly harmless Dr Kitts added that it was outrageous that the public should be constantly dosed with ' medicinal substances ' by persons having no knowledge of their proper use or effects upon the human system.

BRISTOL INSURANCE COMMITTEE —At the last meeting of this committee it was reported that the total number of persons on the 'doctors lists " was now 106 704, an increase of 7000 upon the previous year The number of prescriptions dispensed during 1914 was 382,000, a rate of over 1000 a day

SCARLET FEVER IN BELFAST —The attempt to limit the spread of scarlet fever in Belfast by closing the public schools last Christmas has not succeeded During the week ended Jan 16th there were 41 notifications of the disease as compared with 37 in the previous week, while in the week ended Jan 23rd 55 cases were notified Indeed, there seems to be a recrudescence of the epidemic which has now prevailed so many years in Belfast In the progress of preventive medicine the inability to restrict scarlet fever is the most striking exception.

valuable in the prevention of recurrences, and suggests that prophylactic vaccination against infections of the upper respiratory tract deserves more attention He states that his own experience indicates that most persons who suffer from frequent colds are susceptible to one particular organism with which they are constantly being reinfected Dr Cecil's paper is an interesting and practical contribution to a subject of general interest

ON Wednesday next, Feb 17th, at 5 P M, before the Historical Section of the Royal Society of Medicine, Sir Alexander Simpson, of Edinburgh, will read a paper on *Jean Astruc (1684–1766)*, of the Montpellier School, the historian of syphilis, but nowadays more famous in theological circles as the founder of the higher biblical criticism This is the aspect which will be specially considered, we understand, by Sir Alexander Simpson

THE Morison lectures will be delivered before the Royal College of Physicians of Edinburgh by Dr W H B Stoddart within the hall of the College, 9, Queen street, Edinburgh, on Monday, Wednesday, and Friday, March 8th, 10th, and 12th, commencing each day at 5 o clock P M The subject of the lectures will be the New Psychiatry

THE annual meeting of the British Medical Association, which was to have been held at Cambridge this summer, will not take place The statutory annual general meeting of the Association and the annual meeting of Representatives will, however, be held

MEDICINE AND THE LAW

Medical Certificates and the Education Authorities

AT the Bangor police court recently a summons taken out by the education authority against Ernest Kenrick, the father of a boy who had been kept back from school on the ground of ill health, was dismissed by the bench after hearing the evidence of Mr Helsby, the boy's medical attendant Mr Helsby stated that in his opinion the boy was too delicate to attend school, and he had advised that he should be kept at home during the winter He had given no certificate because he did not think that the education authority could compel parents to obtain and pay for medical certificates in such circumstances, and he knew that the authority did not pay for them In other districts where the education authority paid for certificates he had given them He was always willing to give the required information to school attendance officers The clerk to the magistrates advised the bench that it was doubtful whether the education authority had any right to put parents to the expense of obtaining medical certificates, especially as the attendance officers could always call upon the medical men He advised the magistrates that they had no option but to dismiss the case Mr Helsby explained that he might spend a great deal of time in writing certificates which the majority of parents could not afford to pay for, and that he attended the court in order to maintain his position on the question of principle He is to be congratulated upon having done so with complete success, and it is to be noted that his conduct in the matter was not only legally correct but reasonable and conciliatory, as he was willing to give verbal information to the attendance officer Presumably that official would not find it necessary to call upon the medical man in all cases where illness was alleged as a ground for failure on the part of a pupil to attend school, but would satisfy himself as to the fact of illness by a visit to the child's home Otherwise the tax of personal answer to inquiries would fall as heavily upon the medical man as that of signing certificates without remuneration It would be fairer and more businesslike if all education authorities adopted a uniform practice of requiring and paying for certificates in cases where any uncertainty indicates that they are desirable

Prescription by Telephone

At an inquest at Burton on Trent lately it was proved that death had been caused by the error of a dispenser to whom the medical man attending the deceased had telephoned, instructing him to send a solution of a certain drug containing 1/75th of a grain for hypodermic injection. In taking down the message the dispenser mistook 1/75 for 0·75, and adopted the latter figure in preparing the solution, with the result recorded The mistake should be noted, as all of us who use the telephone are familiar with the mistakes made in telephoning with regard to figures, even when the listener is a practised operator

A Pernicious Quack Sentenced

Arthur Denison Light, described as principal of the British Health Institute and publisher of a periodical called "Power, Purity, and Progress was sentenced to three months' imprisonment at the Old Bailey recently upon a charge of attempting to obtain money by false pretences Light, against whom *Truth* had frequently warned the public, pretended to treat diseases of the sexual organs and sold books and appliances of the character usual with such gentry One of Light's ingenious devices was to offer to make examinations of urine free of charge He was met here by the ingenuity of a detective, Inspector Wagstaff, who submitted an example consisting of cold tea and soap, and was informed that the patient supposed to have passed it was suffering from catarrh of the bladder Inspector Wagstaff and a Mr Leader, a member of a young men's association called the 'Alliance of Honour," who got into communication with the prisoner and placed the correspondence in the hands of the police, are to be congratulated upon having secured for him a sentence which, if inadequate, will serve as a warning to him and others

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND —The next meeting of this association will be held at 11, Chandos street Cavendish square London, W, at 3 15 P M on Thursday next Feb 18th under the presidency of Dr David G Thomson A paper will be read on Meningo-Vascular Syphilis by Dr Roy M Stewart with lantern demonstration. There will be no quarterly dinner

LITERARY INTELLIGENCE —Messrs Smith, Elder, and Co announce for publication under the title of "The Minor Horrors of War" a number of articles which have appeared since the beginning of the war in the *British Medical Journal* by Professor A E Shipley the Master of Christ's College Cambridge These articles deal with various insect and other pests which cause discomfort and often disease amongst our troops now fighting in all quarters of the globe should come upon them for gratuitous advice This is all the harder to bear as so many patients who used to give reasonable fees are now so impoverished that they really cannot pay anything There is as much, indeed more work to be done, but much less to receive than formerly Thus I called on a non panel doctor who I found had been kept from his dinner by nine army dependents After giving them gratuitous advice a tenth visitor came, but instead of a paying patient he proved to be the water rate collector

After-effects of the Air Bombs

It may not, perhaps, be generally realised that the airship bombs have materially increased the amount of work falling upon the medical practitioners It is not the casualties that count two killed three wounded, and minor injuries make but little difference in the total number of patients ill from all causes But there has been a great amount of illness and some deaths among those who were not struck People with weak hearts, startled by the noise and alarm, had violent attacks of palpitation, and several of the deaths a few days after the bombardment were due to the shock. Then there are the highly nervous or neurotic persons One case was that of a woman who could not be induced to sit still but was constantly springing to her feet pacing up and down the room, wondering what she would do if Zeppelins dropped more bombs In another patient the pulse, previously normal continued beating at 105 per minute a fortnight after the explosions These certainly did make a very great noise and being absolutely unexpected were all the more startling Now that the people are a little more accustomed to such aggression it is probable that another attack would occasion much less disturbance. Nevertheless, the emotion they cause must seriously affect persons with weak hearts or highly nervous temperaments.

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

THE undermentioned has been granted a temporary commission as Surgeon in His Majesty's Fleet Arthur Ernest Des

The following appointments have been notified —Staff-Surgeon B R Bickford to the *Pembroke*, additional Temporary Surgeons G M Oakden to the *Prince George* D R. Bedell Sivright and G S Aspinall to the *Victory* additional, for Haslar Hospital W B Cunningham and W L Glegg to the *Pembroke* additional, for Chatham Hospital all as additional medical officers A. G Stewart and D S MacKnight to the *Vivid*, additional, for disposal

ROYAL NAVAL VOLUNTEER RESERVE

Surgeon W H. Bleaden to the *Pembroke* additional

ARMY MEDICAL SERVICE.

Colonel John C Culling is retained on the Active List under the provisions of Article 120 Royal Warrant for Pay and Promotion, 1913, and to be supernumerary (dated Feb 7th)

ROYAL ARMY MEDICAL CORPS

Brevet Colonel Frederick Smith, D S O is retained on the Active List under Article 120 Royal Warrant for Pay and Promotion and to be Supernumerary (dated Feb 8th)

The undermentioned are granted temporary rank as follows —To be Lieutenant Colonel Dated Jan 19th Robert Thomson Leiper To be Lieutenants Dated Jan. 19th Reginald Percy Cockin and John Gordon Thomson

The undermentioned relinquish their temporary commissions with the Allied Forces Base Hospital —Dated Feb 1st Major Arthur G Whitehorne Cole, Major Barnard Hudson Major Philip M Heath Captain Ernest D Roberts Lieutenant Oswald T Dinnick and Lieutenant William M S Robinson

Sydney George Leyland Catchlove to be temporary Captain (dated Jan 11th)

Lieutenant Gwilym L Pierce relinquishes his temporary commission (dated Jan 23rd)

Temporary Lieutenant James G Ferguson resigns his commission (dated Feb 4th)

The undermentioned to be temporary Lieutenants —Dated Jan 16th Dominic Francis Curran John Hastings Glover William Pritchard Airey, and James Morrison Dated Jan 18th Herbert William Fankhausen James Churchill Dunn Wilfred Conrad Stanley Wood Donald Watson Fergus Hay Young George Allan Maling Stanislaus Reader Walter Netherwood Rishworth, Leonard Andersen Pearce Hurt and Samuel Ridley Mackenzie Dated Jan 20th Charles Patrick Valentine MacCormack Archer Ryland Charles James Glasson, James Ninian George William McMorris, and Henry William Doll Dated Jan 21st: James Tate, Frank Llewellyn Gill, William Alfred Taylor, Charles Birch Arthur William Hunter Donaldson, Henry Sydney Colchester Hooper, John Frederick Venables, Edward Benjamin Sunderland Clive Watney Roe, Frank Cyril Greig, John Phillips Blockley Desmond William Beamish, William Leslie, Robert Walpole Murphy, James Parker Arthur Poole, Gerald Robinson, Cyril Carlyle Beatty, Patrick Steele, William Armour Brown Reginald Hannay Fothergill, and Desmond Manus MacManus. Dated Jan 22nd William Gerald Ridgway, Robert Aikin Wright, James Hill, Bevil Molesworth Collard, Thomas Joseph Redmond Maguire, and Harold Myrie Cory

SPECIAL RESERVE OF OFFICERS

Royal Army Medical Corps

Lieutenant Robert Dunlop Goldie to be Captain

Supplementary to Regular Units or Corps Royal Army Medical Corps

The undermentioned Lieutenants are confirmed in their rank John S Dockrill Henry P Whitworth, Thomas H S. Bell, Francis A. Duffield John J D La Touche Joseph H Baird, John J Molyneaux, John Stephenson, James Purdie, Clark Nicholson, William S Wallace Samuel D G McEntire, Gerald G Alderson, Arthur A. Smalley, Wilfrid B. Wood, Francis A. Roddy, Harold A. Crouch, Herbert S Milne John S Pooley, Quentin V B Wallace, William H. Nicholls, Henry Alcock, John Kennedy, and Thomas F Kennedy

The undermentioned to be Lieutenants (on probation) Henry Richard Sheppard, Cadet of the Officers Training Corps, and Robert Harvey Williams, ex-Cadet of the Officers Training Corps.

TERRITORIAL FORCE

Royal Army Medical Corps

2nd London (City of London) Field Ambulance Captain (Honorary Lieutenant in the Army) William E Rielly, from the Territorial Force Reserve, to be Captain

2nd London (City of London) General Hospital Maynard Horne to be Captain (temporary) Lieutenant Horace G L Haynes from 2nd North Midland Field Ambulance, to be Lieutenant

Sanitary Service Alfred Ernest Williams to be Captain, whose services will be available on mobilisation

3rd Northern General Hospital Norton Milner to be Captain, whose services will be available on mobilisation.

1st Southern General Hospital Robert Beatson Dennis Hird to be Captain, whose services will be available on mobilisation

South Eastern Mounted Brigade Field Ambulance Captain Charles Holt Caldicott, from Attached to Units other than Medical Units to be Captain Captain Arthur Lewis Heiser, from Attached to Units other than Medical Units, to be Captain

2nd Home Counties Field Ambulance Captain James Dundas, from Sanitary Service, to be Captain. Lieutenant Ernest Mannering Morris, from Attached to Units other than Medical Units, to be Lieutenant.

1st London (City of London) Sanitary Company Andrew Alexander McWhan to be Lieutenant.

2nd North Midland Field Ambulance Lieutenant Hubert Pinto-Leite, from the 2nd London (City of London) Field Ambulance, to be Lieutenant

2nd Lowland Field Ambulance To be Lieutenants Stephen Anderson MacPhee and Colin Cameron Philip (late Cadet, Edinburgh University Contingent, Senior Division, Officers Training Corps)

2nd Northumbrian Field Ambulance William Smith to be Lieutenant

Attached to Units other than Medical Units—To be Lieutenants William Brown and William Alfred Phillipps

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN the 96 English and Welsh towns with populations exceeding 50 000 persons at the last census, 8650 births and 6995 deaths were registered during the week ended Saturday, Feb 6th The annual rate of mortality in these towns, which had been 18 8, 18·0 and 19·2 per 1000 in the three preceding weeks, further rose in the week under notice to 20·1 per 1000 of their aggregate population estimated at 18 134,239 persons at the middle of 1914 During the first five weeks of the current quarter the mean annual death-rate in these towns averaged 19 1 against 20·0 per 1000 in London The annual death rate last week ranged from 10·3 in Ilford, 10·9 in Swindon 11 8 in Southampton 12·5 in Edmonton and in Warrington and 12·9 in Wakefield to 29·9 in Great Yarmouth, 31·6 in Brighton 32 5 in Merthyr Tydfil, 35 2 in Stockton-on Tees, and 40·7 in Cambridge

MEDICAL PRACTICE ON THE EAST COAST THE POSITION AT GREAT YARMOUTH

(BY OUR SPECIAL COMMISSIONER)

Great Yarmouth Feb. 8th.

To counterbalance the inevitable economical pressure felt by a nation at war we have generally some communities more thriving than others, because they can provide some of the varied material—ships, guns, weapons, clothes—needed for the prosecution of hostilities, other localities receiving no such set-off will necessarily suffer as more and more money is consumed Prominent among the English towns which have to bear the burden of war time stands Great Yarmouth, which has been attacked directly and twice by the enemy, and suffers indirectly by the collapse of its main sources of income Fortunately, the first attack, a bombardment, did no harm Presumably the German ships mistook the distance, for all their shells fell short of the town This first attack occurred, it will be remembered, at the beginning of November, and its memory was fading away when on the night of Jan 19th airships hovered over the town dropping bombs—this time with fatal effect in that several lives were lost, but no great destruction of buildings occurred Financially speaking, rumour did vastly more harm to Yarmouth than the German bombs

The netting of fish and the letting of lodgings are the principal sources of income at Yarmouth, and the war has dealt hardly with both A considerable proportion of the inhabitants rent houses with the intention to secure lodgers for a part of them, and render themselves liable to pay rent and rates far and away above what they would pay in either direction for their personal use Of course, they count on making up the difference advantageously by letting rooms or by taking in boarders The season at Yarmouth is very short, it reaches its climax in September and was commencing at the end of July War was declared on Tuesday, August 4th Of the visitors who were already at Yarmouth hardly any remained beyond the end of that week and none came to take their place the following week Gradually braver spirits returned, but the town never recovered its holiday population as some more fortunate watering places further south appear to have done Perhaps if there had been fewer sinister rumours floating about, the season might not have been so completely spoilt, but every parent who looked at an atlas recognised that if attack was possible Yarmouth was a very vulnerable spot, and decided not to venture there with children Mere digging of trenches would not have frightened the public away from Yarmouth any more than it did from Broadstairs But being nearly opposite the German naval base, it was but too correct to conclude that Yarmouth would be attacked if attack became feasible, while experts were aware of the possibility of a dash from fast enemy cruisers Therefore, those who, in spite of the war were not disposed to forego their seaside holiday selected some place that seemed less exposed than Yarmouth

The Effect on the Local Industries

The next source of income in Yarmouth is the fishing industry, especially the herring trade. This gives employment to a large number of fishermen, and also to regiments of Scotch women, who follow the fishing smacks along the coast to clean and pack the herrings They arrive just after the sea bathing season concludes and in the South Side near the fish-docks fill the lodgings abandoned by the holiday folks But as most of the herrings are packed in barrels, preserved in brine, and exported to the North Sea and Baltic ports this trade is paralysed by the war It so happens that the herring women have found during the collapse of their trade a valuable method of earning money Exposed to all weathers, they know how to knit themselves warm woollen underclothing To-day they can find employment knitting clothes for the soldiers at the front, but they do this at home in Scotland, not at Yarmouth. The poorer lodging house keepers, those for instance who used to receive the women employed in fish cleaning are doing very well in billeting soldiers On their side the soldiers are more comfortable than usual, for being housed by lodging house keepers the cooking and attendance generally are better than in private families which do not make a business of receiving strangers

The Prosperous Inhabitants Suffer Most

The lodging house keepers, however, who are able to balance the loss of their ordinary business by attending to soldiers do not belong to the class which best pays its medical attendants The central and richer part of the town suffers most, and its inhabitants are not likely to ask for help Employees of different sorts in commercial spheres provided modest payments for board and lodging during the winter months on condition that they retired to small rooms during the summer holiday rush. Last year there was no summer rush, and many of these winter clients have enlisted. The health authorities, I found, do not think there is as much poverty as usual among the labouring class and those sections of the community who in normal times suffer most. But other sections who, as a rule do not suffer at all are badly hit, and they are the best ratepayers and the medical practitioners' principal source of income The municipal authorities are greatly concerned, for they do not like to prosecute good citizens The medical practitioner feels the same compunction about pressing for his fees Thus one medical practitioner told me that a patient could not pay what she owed him because her lodger owed her £18, and the lodger could not pay because his occupation had practically ceased at the outbreak of war Then those connected with the law have little or nothing to do No one is going to institute legal proceedings while the war lasts Jewellers, tailors dressmakers all suffer The war is a good reason for wearing out all the old clothes Persons who have private means cannot realise their investments, and those who have placed money in German or Austrian enterprises may never see any of it again Tradespeople who deal in objects that are not absolutely necessary do very little trade, and it will be seen that these are just the very classes among whom medical practitioners find their best paying patients Even those who have money feel unsafe and think it more prudent to economise Therefore they only send for their doctor when it is absolutely necessary Or, worse still, they profit by the fact that they have the means to leave the town altogether, though this is not the general rule

The personal economy and the cessation of trade in certain directions could of course be paralleled all over the country, but in Yarmouth the depression is accentuated by the collapse of the two great industries

Vast Gratuitous Medical Attendance

The poorer sections of the community are if anything better off than before the war The labourers readily find employment, while many of them have enlisted, and there is a good deal to do for those who remain. But the abolition of the militia by the establishment of the Special Reserve has been a great loss to the town of Yarmouth The Norfolk Militia was almost a crack regiment His late Majesty Edward VII, was their colonel, and he used to come down to Yarmouth to review them, thus bringing much money to the town Many of the old militiamen accepted a small fee to become reservists From the town of Yarmouth alone, out of its 57 000 inhabitants no less than 500 were called to the flag as reservists A large proportion not only of these reservists but of those who enlisted since the beginning of the war, were insured persons, but their wives and children were paying patients Now this important source of income is lost to the profession for the wives and children of those with the Flag are being attended in the main gratuitously

The Dependents of the Soldiers

Yielding to a generous and patriotic impulse practically all the practitioners at Yarmouth agreed to attend gratuitously the dependents of those who enlisted The chemists, on their side, offered not to charge for the work of dispensing the drugs and the Prince of Wales's Relief Fund was looked to to reimburse the bare cost of the drugs consumed. But quite a large proportion of these dependents are better off than they were before the outbreak of war The allowance they get from the War Office is in many cases higher than what their husbands could afford to give before they enlisted and yet in those days they had to pay for medical attendance Now the dependents can claim the services not only of the panel but of the non panel doctors and neither chemist nor doctor receives any remuneration The Yarmouth practitioners are beginning to wonder why dependents who are generally speaking, better off than they were formerly

CANADA

(From our own Correspondent)

Aid for the Belgian Doctors and Pharmacists

At the request of Sir Rickman Godlee, Dr Herbert A. Bruce, Toronto, has successfully organised a strong and representative committee of the leading physicians and pharmacists of Canada, having for its object the relief of Belgian doctors and pharmacists The central committee is located in Toronto, where meetings are being held regularly and the work prosecuted with vigour Dr Walter McKeown acts as secretary and Dr David Gibb Wishart as treasurer Its personnel consists of presidents of the national and provincial medical societies, presidents of the various Medical Councils, the editors of the medical journals, and the deans of the medical departments of the universities Although just organised there has already been made a number of substantial contributions from the members of the professions in Toronto as well as from some private citizens

Medical Reciprocity in Ontario with Great Britain

Late in December a special meeting of the newly elected Medical Council of Ontario was called in Toronto, and the subject of medical reciprocity was fully discussed It was resolved unanimously to approve of the principle of medical reciprocity, and the Legislative Committee of the Council was instructed to lay the matter before the Ontario Legislature for sanction, and also to bring the proposition before the General Medical Council of the United Kingdom When Ontario falls in line that will make five provinces in Canada having reciprocity with the motherland—namely, Prince Edward Island, Nova Scotia, New Brunswick, and Quebec It will only remain then for the four western provinces to complete the arrangement for all Canada.

The Canadian Medical Profession and the War

It is reported that already Canada has 160 medical men serving the Empire either in England or at the front, and many more are in line for the front with Canada's second contingent Many of the leading men have volunteered for service, and others have actually taken training Altogether in Toronto, after the second contingent has been supplied, there is a waiting list of nearly 200 McGill Medical Department will send in the spring a complete hospital staff from the members of the medical faculty and the student body, the nurses being selected from the various hospitals of the city Dean Birkett will be in command Queen's University Medical Department, Kingston, Ontario, has also offered a complete general hospital. And now comes another offer from the French Canadian medical men and students at Laval University, Montreal, for still another general hospital. Not only for active service, but for relief, the medical profession of Canada is well to the fore An example of what medical societies are doing is seen in the case of a recently organised society in Toronto, the Æsculapian Club, of some 70 members This society has practically donated all its reserve funds to the Patriotic Fund, $100 Ladies Comforts for Soldiers Fund, $50, Belgian Relief $200 and for surgical supplies to wounded in Northern France and Belgium, $50

Toronto University and German Professors

The University of Toronto has been very much in the public eye during the past two or three months owing to having retained on its teaching staff three German professors One of the governors, a prominent financier, died suddenly, but left a letter which deprecated retaining these professors on the staff in war time, or of even permitting them to retain their connexion with the University, although released from their duties on full pay Still another leading financier and public man, Sir Edmund Osler, protested, and resigned over the matter The result has been the departure of two of the German professors for the United States, whilst the third remained in Toronto and took out naturalisation papers So far that professor has been allowed to provide a substitute This has brought the president of the University, whose rule is practically predominant, owing to recent legislation, into difficulties

Queen's University and the War

When the war began no university in Canada responded to the call so promptly or did so well as that of Queen s at Kingston This was due to the splendid work of the Faculty of Applied Science A company of engineers was sent to Valcartier, which was the only organised contingent at that camp Of the work they did there professional soldiers and others qualified to speak have done so in the highest terms With the second Canadian contingent another well trained corps will go, being again the only Canadian university to send an organised unit Of the 80 members of this unit 70 are members of the Kingston School of Mining, the other 10 being picked from the Faculties of Arts and Medicine

THE VALUE OF TINCTURE OF IODINE AS A BACTERICIDE

To the Editor of The Lancet.

Sir,—In The Lancet of Jan. 2nd Dr Alexander Brown asks if the tincture of iodine, or a 2 per cent solution, can destroy bacteria and their spores Since there are several hundred varieties of bacteria recorded as excitants of disease, and as there may be wide differences in their resistance to antiseptics, much more experimental work must be undertaken before a comprehensive answer to Dr Brown's inquiry can be given. The following experiments, which I made two years ago, though they offer a very partial answer to the question, may be of interest at the present moment I had been asked by Dr J R. Bentley, of Limpsfield, to suggest a douche for a case of cystitis The patient had had his prostate removed, to his great relief, but his cystitis persisted despite a partial relief from an autogenous vaccine of the B coli present in his urine The failure to clear up the infection was attributed to the sacculated condition of the bladder An emulsion of living B coli, obtained from a catheter specimen of the urine, was divided into six equal portions To each portion an equal volume of solution of tincture of iodine in varying strengths, distilled water being the diluent, was added. Thus—

Tubule No 1 = 2% tincture of iodine in distilled water
" No 2 = 1% " " " "
" No 3 = 0 5% " " " "
" No 4 = 0 25% " " " "
" No 5 = 0 125% " " " "
" No 6 = 0·0625% " " " "

The 6995 deaths from all causes were 302 in excess of the number in the previous week, and included 513 which were referred to the principal epidemic diseases, against numbers increasing from 454 to 483 in the three preceding weeks Of these 513 deaths, 210 resulted from measles, 123 from whooping-cough, 72 from diphtheria, 68 from infantile diarrhœal diseases, 22 from scarlet fever, 17 from enteric fever, and 1 from small pox. The mean annual death rate from these diseases was equal to 1 5 against 1·4 per 1000, in each of the two preceding weeks The deaths attributed to measles, which had been 195, 206, and 191 in the three preceding weeks, rose to 210 last week, and caused the highest annual death rates of 2 5 in Plymouth, 2 7 in Grimsby, 2 8 in Wigan, 3 1 in Gateshead, 3 5 in Darlington, 3 6 in Cambridge, 4 1 in St Helens, 4 8 in Rotherham, 6 7 in Merthyr Tydfil, and 9 7 in Stockton-on-Tees The deaths referred to whooping-cough, which had been 76, 93, and 99 in the three preceding weeks, further rose to 123 last week, the highest recorded rates from this cause were 1 2 in Blackburn, 1 7 in Reading and in Bristol, 1 9 in Rhondda, 2 4 in Sunderland, 3 1 in Gloucester, and 3 7 in Merthyr Tydfil The fatal cases of diphtheria, which had been 63, 83, and 77 in the three preceding weeks, further fell to 72 last week and included 16 in London, 4 each in Southampton and Halifax, and 3 each in Tottenham, West Ham, Stoke-on-Trent, Birmingham, Manchester, Salford, and Bradford The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 75, 62, and 73 in the three preceding weeks, fell to 68 last week, of which 13 were registered in London, 7 in Liverpool, 5 in Bristol and 4 in Manchester The deaths referred to scarlet fever, which had been 34, 23, and 31 in the three preceding weeks, fell to 22 last week, of which 7 were recorded in London The fatal cases of enteric fever, which had been 11, 12, and 12 in the three preceding weeks, rose to 17 last week, and included 5 in London and 2 each in Wallasey, Manchester, and Leeds The death from small pox was registered in London, and belonged to the borough of Fulham

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily declined from 5035 to 3647 in the ten preceding weeks, had further fallen to 3395 on Saturday last, 365 new cases were admitted during the week, against 338, 303, and 326 in the three preceding weeks These hospitals also contained 1659 cases of diphtheria, 175 of measles, 56 of enteric fever, and 27 of whooping-cough, but not one of small pox. The 1859 deaths from all causes in London were 101 in excess of the number in the previous week, and corresponded to an annual death rate of 21 5 per 1000 The deaths referred to diseases of the respiratory system, which had been 472, 417, and 450 in the three preceding weeks, further rose to 497 last week, and were 150 above the number recorded in the corresponding week of last year

Of the 6995 deaths from all causes, 216 resulted from different forms of violence and 530 were the subject of coroners' inquests, while 1864 occurred in public institutions The causes of 61, or 0·9 per cent, of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest All the causes of death were duly certified in London and in its 14 suburban districts, in Sheffield, Leeds, Bristol, Bradford, Hull, and in 51 other smaller towns Of the 61 uncertified causes of death 15 were registered in Birmingham, 11 in Liverpool, 5 each in Manchester and Preston, and 2 each in West Bromwich, Bootle, Blackburn, and Darlington

HEALTH OF SCOTCH TOWNS

In the 16 largest Scotch towns with an aggregate population estimated at 2 345 500 persons at the middle of this year, 1224 births and 1036 deaths were registered during the week ended Saturday Feb 6th The annual rate of mortality in these towns which had been 22 8, 21 7, and 22·4 per 1000 in the three preceding weeks further rose to 24 1 per 1000 in the week under notice During the first five weeks of the current quarter the mean annual death rate in these towns averaged 23 1, against 19 1 per 1000 in the large English towns Among the several towns the death rate last week ranged from 16·4 in Clydebank, 17·0 in Kilmarnock, and 20 8 in Edinburgh, to 29·5 in Coatbridge, 32 3 in Perth, and 39 1 in Dundee

The 1036 deaths from all causes were 77 in excess of the number in the previous week and included 147 which were referred to the principal epidemic diseases, against numbers rising from 92 to 128 in the three preceding weeks Of these 147 deaths, 86 resulted from whooping-cough, 17 from scarlet fever, 16 from infantile diarrhœal diseases 13 each from measles and diphtheria and 2 from enteric fever but not one from small pox. The mean annual death rate from these diseases was equal to 3 3 against 1·5 per 1000 in the large English towns The deaths attributed to whooping cough, which had increased from 23 to 82 in the six preceding weeks, further rose to 85 last week, of which 47 occurred in Glasgow, 22 in Dundee 6 in Edinburgh, 4 in Motherwell, and 3 in Greenock. The deaths referred to scarlet fever, which had been 16, and 12 in the three preceding weeks, rose to 17 las week, and included 9 in Glasgow and 2 each in Edinburgh, Hamilton, and Clydebank The fatal cases of diarrhœa and enteritis (among infants under 2 years) which had been 7, 8 and 15 in the three preceding weeks further rose to 16 last week, 8 deaths belonged to Glasgow 3 to Dundee, and 2 to Hamilton The deaths attributed to measles, which had averaged 7 in the four preceding weeks, rose to 13, of which 11 occurred in Dundee The deaths referred to diphtheria which had been 10, 8 and 10 in the three preceding weeks, further rose to 13 last week, and comprised 4 each in Glasgow and Edinburgh, 2 each in Aberdeen and Paisley, and 1 in Ayr The fatal cases of enteric fever were recorded in Glasgow and Edinburgh

The deaths referred to diseases of the respiratory system, which had been 275, 238, and 272 in the three preceding weeks, further rose to 302 in the week under notice, and were 123 in excess of the number recorded in the corresponding week of last year Thirty six deaths were associated with different forms of violence, against 30 in each of the two preceding weeks

HEALTH OF IRISH TOWNS

In the 27 town districts of Ireland with an aggregate population estimated at 1,212,380 persons at the middle of this year, 661 births and 609 deaths were registered during the week ended Saturday, Feb 6th The annual rate of mortality in these towns, which had been 24·4, 24·0, and 24 7 per 1000 in the three preceding weeks further rose to 26 2 per 1000 in the week under notice During the first five weeks of the current quarter the mean annual death rate in these towns averaged 25 2, against 19 1 and 23 1 per 1000 in the English and Scotch towns respectively The annual death rate last week was equal to 30 5 in Dublin (against 21 5 in London and 22 7 in Glasgow) 25 2 in Belfast, 27 9 in Cork, 29 1 in Londonderry, 23·0 in Limerick and 15 2 in Waterford while in the 21 smaller towns the mean death rate was 20 7 per 1000

The 609 deaths from all causes were 34 in excess of the number in the previous week, and included 38 which were referred to the principal epidemic diseases, against numbers declining from 48 to 32 in the three preceding weeks Of these 38 deaths 13 resulted from whooping cough, 10 from infantile diarrhœal diseases 6 from measles 5 from scarlet fever, 3 from diphtheria, and 1 from enteric fever, but not one from small pox. The mean annual death rate from these diseases was equal to 1·6 against 1 5 and 3 3 per 1000 in the English and Scotch towns respectively The deaths attributed to whooping-cough which had been 10, 9, and 11 in the three preceding weeks, further rose to 13 last week, of which 7 occurred in Dublin and 4 in Belfast The deaths of infants (under 2 years) referred to diarrhœa and enteritis which had been 14, 4, and 8 in the three preceding weeks, rose to 10 last week, and comprised 6 in Dublin 3 in Belfast and 1 in Larne The fatal cases of measles, which had been 12 15, and 4 in the three preceding weeks, rose to 6 last week, of which 4 belonged to Belfast The 5 deaths attributed to scarlet fever were slightly in excess of the average in recent weeks, and comprised 4 in Belfast and 1 in Waterford Of the 3 deaths referred to diphtheria, 2 occurred in Dublin and 1 in Cork The fatal case of enteric fever was registered in Limerick In addition to the above deaths, 3 fatal cases of typhus were recorded in Londonderry and 1 in Dublin

The deaths referred to diseases of the respiratory system which had been 164 137, and 160 in the three preceding weeks, further rose to 172 in the week under notice Of the 609 deaths from all causes, 173 or 28 per cent, occurred in public institutions and 6 resulted from different forms of violence The causes of 27, or 4·4 per cent of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest in the English towns the proportion of uncertified causes did not exceed 0 9 per cent

---

THE IRISH ROYAL COLLEGES AND BELGIAN STUDENTS —The Royal Colleges in Ireland have agreed upon two important concessions to Belgian medical students who are in forced exile from their own country In the first place the curriculum of the four Belgian Universities will be accepted as qualifying to sit for the examinations of the Conjoint Committee of the Royal Colleges In the second place, the Conjoint Committee is authorised to remit the fees in the case of Belgian students who are unable to pay them men to the voluntary hospitals and double the staff of such This number can be increased by 10,000 in one week by appointing local district visiting staffs At Liverpool the majority of the visiting doctors are entitled to charge full fees to hospital patients occupying pay beds and pay wards Local doctors will not be excluded from making a fair wage if appointed. Only a little common sense is required to meet the "scarcity of doctors" bogey Will the "men in possession" agree?

I am, Sir, yours faithfully,

Liverpool, Feb 8th 1915. R R RENTOUL, M D

TUBERCULIN TREATMENT OF PULMONARY TUBERCULOSIS

To the Editor of THE LANCET

SIR,—In Dr E G Glover's communication on this subject in THE LANCET of Feb 6th occurs the following statement —

> There is one other point which deserves notice, although perhaps it is a minor one, and it is that the dangers noted after reactions—i.e , extension of disease, increased activity, pleurisy, and pneumothorax—are unfortunately, as the Registrar General will testify, the dangers of the disease itself.

Such a remark has no bearing on the danger or otherwise of administering tuberculin. No sound critic of tuberculin ever imputed to tuberculin a capacity to do more than increase the disease, and because the disease spreads and produces the above results in many untreated cases, this in no way removes tuberculin from the list of agents which may hasten the above calamities

I am, Sir, yours faithfully,

Ayrshire Sanatorium Feb 6th 1915 EDWARD E PREST

LEECHES AND THE WAR

To the Editor of THE LANCET

SIR —With regard to Mr J D Marshall's offer in THE LANCET of Feb 6th, it may be of interest to state that leeches of the official variety are obtainable to a limited extent through the ordinary trade channels at a cost less than one fourth that mentioned by Mr Marshall for Limnatis granulosa This institution received a small number of leeches of French origin this week

I am, Sir, yours faithfully

London Hospital Feb. 6th 1915. F A HOCKING

⁂ But the price of a leech might vary with its capacity — ED L.

THE DEARER LOAF

To the Editor of THE LANCET

SIR,—As a result of the appearance of your leading article with this title on Jan. 30th, I have been asked by the Corn Products Company, Limited, to forward you some loaves made from a mixture of wheaten flour and cornflour My son, Mr William C Jago, who now controls the Jago Laboratories, has had some loaves baked for me in a test bakery Samples of these, numbered 1, 2, 3, and 4, were forwarded to you yesterday

The following are particulars of the mixtures from which the respective loaves were made 1 London Town household flour only, with salt yeast, and water 2 Mixture of 90 parts same flour with 10 parts cornflour, in addition gelatinised cornflour at the rate of 4 lb to the sack of 280 lb , and dry corn starch sugar at the rate of 2 lb to the sack were used Other ingredients as before 3 Mixture of 80 parts same flour with 20 parts cornflour Additions, &c , as in No 2 4 Mixture of 66 parts same flour with 20 parts cornflour and 14 parts peaflour Additions, &c , as in No 2 The volumes of the resultant loaves, each made from 560 grammes of the flour or flour mixture, were as follows (1) 2839 c c., (2) 2676 c c , (3) 2593 c c , (4) 2022 c.c The mixed flour loaves were all smaller than that from unmixed flour, but in every case they were of fair volume and good open texture The loaves themselves will, however, best show you the general characters of the resultant bread I think you will agree that in colour and general appearance Nos 2 and 3 are fairly equal to No 1, and would prove quite as digestible The employment of No 2 mixture would increase the available supply of breadstuffs from 100 parts to 111 parts, while in the case of No 3 the increase would be from 100 parts to 125 parts

In the case of No 4 the object of the experiment was somewhat different—viz., to prepare bread that should have about the same protein value as the white flour used in the preceding *mixtures A sample* of the flour yielded 10 per cent of protein on analysis Taking the protein content of peaflour at 25 per cent., a mixture of two parts of peaflour to three parts of cornflour would also contain 10 per cent of protein, and might therefore be used in any desired proportion with the wheaten flour without altering its protein content In the case of No 4, two parts of wheaten flour were taken to one part of the pea and corn flour mixture This represents a somewhat large addition to a flour which, to start with, was somewhat on the weak side The dough was naturally very friable in the handling, but nevertheless made a fair loaf. Again, the sample itself will best show you the nature of the bread. (In all cases please make allowance for the staleness and effects of packing on the loaves when they reach you) I think you will agree that this bread is not at all unpleasant in either appearance or flavour Judging from its physical character I should say such bread would be very digestible and its proteins capable of very good absorption. In all probability the ratio of absorption would be slightly higher than is the case of the white bread. The use of such a mixture, if necessity arose, would raise the amount of available bread stuffs from 100 to 150 parts and with no loss of nutritive value

At present market prices the No 4 mixture works out slightly lower in price than the flour There is not likely to be any shortage in the world's supply of cornflour, and in addition to peas there are lentils and soya beans to draw on as auxiliary sources of protein. The latter especially is exceedingly rich in flesh formers, and yields a flour which is light in colour and of pleasant flavour

I am, Sir, yours faithfully,

Hove Sussex Feb 6th 1915 WILLIAM JAGO

⁂ The results are quite interesting The loaves received appeared to us to be quite acceptable in regard to texture, flavour, and appearance —ED L.

LONDON UNIVERSITY EXAMINATIONS AND THE NEW PHARMACOPŒIA —The regulations for the second examination for medical degrees Part II., have been amended by the insertion of the following footnote At the examinations in pharmacology held in March and July 1915 students will be permitted to base their replies either on the old or on the new edition of the Pharmacopœia provided that they shall be required to state on which edition such replies are based In and after March 1916, replies must be based on the new edition of the Pharmacopœia.

These tubules were at once placed in the incubator at 37° for five minutes only and directly afterwards an equal volume from each was pipetted into a tube of gelose The inoculated culture tubes were incubated at 37° for 24 hours and no growth occurred in any of them The deduction was that the tincture of iodine solution, in each of six strengths (2 per cent down to 0 0625 per cent), had proved an effective bactericide Irrigation of the bladder with 0 2 per cent strength was recommended This proved to be quite unirritating, and cultures taken on the following day showed marked diminution in the number of colonies of B coli

The coliform group of bacteria is a very large one, very widely spread, and plays a most important rôle in many infections, though perhaps not often the leading part Its vitality in most strains is above that of many other common pathogenic microbes Yet its resistance, if one may safely argue from the above tests, to iodine solutions falls far below that strength (tincture, or 2 per cent solution) generally employed by surgeons

Some years ago I had considerable experience of very severe accidents amongst the Durham miners Extensive lacerated wounds, always badly contaminated with the highly septic pit dust, were very frequent, and I generally brushed them over freely with tincture of iodine Where this was done subsequent occurrence of suppurating cellulitis was very rare For bad compound fractures I preferred to rely upon free irrigation with 1 in 5000 solution of perchloride of mercury The latter solution never let me down in major midwifery operations, under the most unfavourable sanitary conditions, even when puerperal septicæmia was epidemic in the district, provided that the uterus and vagina were thoroughly irrigated at the conclusion of the labour When, in deference to various authorities, who said that perchloride was futile because it formed a surface coagulum, I abandoned my routine for other antiseptics I not infrequently had serious trouble

With regard to the action of iodine upon spores, my experience is limited to a few of the common, innocuous bacteria of the spore producing species Some of the B vulgatus family occur not infrequently as contaminations in the preparation of vaccines from throat cultures or from pyorrhœa. For three years I have made a practice of adding 0 5 per cent of tincture of iodine to the emulsions after heating for an hour at 55° on three successive days Subsequent cultures have invariably proved sterile, and I have attributed that sterility to the action of the iodine, since spores would probably have survived the comparatively low heat used

I am, Sir, yours faithfully,

H LYON SMITH, M D Durh

Bentinck street, W , Feb 8th 1915

LICE AND RHEUMATISM AMONGST SOLDIERS

To the Editor of THE LANCET

SIR,—I have read with very great interest Sir Lauder Brunton s letter with this title in your issue for Feb 6th, but among the remedies for body lice he does not mention paraffinum liquidum (B P), which can also be obtained in a crude state The B P preparation is very largely used at our cleansing station in Poplar in the treatment of verminous children After the bathing of the children liquid paraffin is smeared on the heads so that any lice may be killed as they are hatched from nits which have not been removed by combing the hair with a fine tooth comb dipped in methylated spirit or by application of the same by dabbing any discovered nits If a little mercury perchloride, half grain to the ounce, is added to the spirit it makes the application more effectual A very common household method of loosening the nit is the application of vinegar or acetic acid Respecting Dr S Monckton Copeman's article on p 273 of the same issue, I have known many mothers use the ordinary paraffin, but this is dangerous the flash point being low, but that of liquid paraffin (B P) is high Two handbills are circulated in the borough of Poplar *re* body and head lice, and the liquid paraffin (B.P) is not only recommended for the head but also, when dried after a bath, for gently rubbing over the whole body, except the face, leaving a thin layer of the liquid

I am, Sir, yours faithfully,

FRED WM ALEXANDER,

Medical Officer of Health Metropolitan Borough of Poplar

Bow-road E , Feb 6th 1915

To the Editor of THE LANCET

SIR,—In THE LANCET of Feb 6th you publish a letter from Sir Lauder Brunton under the above heading in which he enumerates 11 drugs as useful for the cure of the former and sulphur powder applied externally as a remedy for the latter disease

In my book on "The Treatment of Diseases of the Skin," under the chapter on pediculosis, the following paragraph occurs on p 169 "Sulphur wrapped up in a piece of flannel or in a porous bag and worn about the person next to the skin acts in many cases as a preventative" If our soldiers resorted to this very simple remedy they might remain free from both complaints

I am, Sir, yours faithfully,

W KNOWSLEY SIBLEY

Cavendish place W Feb. 7th, 1915

THE SHORTAGE OF RESIDENT MEDICAL OFFICERS

To the Editor of THE LANCET

SIR,—In THE LANCET of Feb 6th Mr W M Wilcox, secretary of the East London Hospital for Sick Children, suggests that there is a shortage of resident doctors Perhaps if a reasonable payment be given the very "alleged" shortage will disappear The local educational authorities now pay not less than £250 to freshly qualified doctors, while the equally fresh tuberculosis medical officers under the National Insurance Acts receive up to £350 I am told that about 3000 doctors have entered their names at the Admiralty and War Office Each accepted will receive about £1 per day on service May I add that many of the steamship companies are now paying their surgeons £15 to £20 per month, a bonus of £50 per annum the right to charge fees to saloon passengers, and admission to membership for the pension fund The present resident doctor at voluntary hospitals is paid a lost dog s wage and is financially on the same degrading level as the Poor law medical officer Even residents in Poor law infirmaries now obtain over £250 per annum, extra fees, with board, lodging, and washing—i e , about £450 Let Mr Wilcox attempt to do away with the dog in the manger policy of doctors now acting as visiting

The War.

THE TROOPS AND ANTITYPHOID INOCULATION

REFERENCE is made in our Parliamentary Intelligence this week to a leaflet on the subject of antityphoid inoculation which is being distributed to the troops The leaflet is addressed "To All Soldiers," and Lord Kitchener himself supplies a preface in these words —

"I commend to the careful attention of every Soldier the following statement, to which, in the interests of the health of the Army, I attach great importance —KITCHENER, F.M"

The statement is as follows —

> In every campaign typhoid fever is a serious element In the South African War there were many more casualties from typhoid fever than from wounds
>
> In the present war the best is being done to prevent typhoid fever by extreme precautions in the matter of water-supply, as well as other sanitary measures, but in spite of this a number of men have been affected by the disease
>
> **Inoculation Gives the Body Power to Resist Infection**
>
> It is a means of protection in the efficiency of which those who have studied the question have complete confidence.
>
> Inoculation has nothing to do with vivisection
>
> The great value of inoculation is shown clearly in the following figures —
>
> **Of the 421 cases in the present campaign among British troops. 305 cases were in men who were NOT INOCULATED within two years.**
>
> **In the 421 cases there have been 35 deaths**
>
> **Of these deaths 34 were men who had NOT BEEN INOCULATED within two years.**
>
> **ONLY ONE DEATH OCCURRED AMONG PATIENTS WHO WERE INOCULATED and that man had only been inoculated once, instead of the proper number of times—namely twice**
>
> For your own sake, for your country's sake, and for the sake of the Army you should not fail to avail yourself of the protection secured by this simple, safe, and well tested measure
>
> Medical officers are always ready and anxious to inoculate any soldier at any time, and the greatest care is taken in doing so With proper care it has never been known to do a man harm

The statement, which seems to be worded in just the right way to impress a soldier audience, is signed by Sir Thomas Barlow, President of the Royal College of Physicians of London, Dr A. H. Freeland Barbour, President of the Royal College of Physicians of Edinburgh, Sir W Watson Cheyne, President of the Royal College of Surgeons of England, Dr E MacDowel Cosgrave, President of the Royal College of Physicians of Ireland, Mr F Conway Dwyer, President of the Royal College of Surgeons in Ireland, Mr J W B Hodsdon, President of the Royal College of Surgeons of Edinburgh, and Sir Frederick Treves, Sergeant Surgeon to H.M the King

THE CASUALTY LIST

The official casualty lists published since our last issue have contained the name of one medical officer, Captain James Alexander Terras Bell, M D, New Zealand Medical Corps, reported as having died in Egypt

MEDICAL PRECAUTIONS AGAINST AIR RAIDS

In an annotation with the above title in THE LANCET of Jan 9th the surgical aspects of an air raid upon London were briefly discussed, and it was stated that a scheme of preparation against such an outrage had been carefully thought out With the sanction of the military and police authorities this scheme has now been elaborated and

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND

THE Fund has during the week received a fair number of subscriptions, conspicuous among them being a cheque from the Ontario Medical Association for £102 13*s* 4*d*

The Liverpool subscriptions, which for the present remain in the hands of the Liverpool Medical Institution, have continued to come in, and a vigorous start is being made in Manchester under the auspices of a strong local committee

CENTRAL EXECUTIVE COMMITTEE

Certain cases of distress have been relieved immediately, on the representation of Dr Clément Philippe, the President of the Société Belge de Médecine et de Pharmacie en Angleterre, and there has been some success in finding work for Belgian practitioners, under the recent privilege of British registration It seems doubtful whether the General Medical Council will be able to reduce or remit the fees of Belgians desiring to register, and it may devolve upon the Fund to advance the money in some cases There was no Belgian doctor found to fill a post where a single man was required, all the available Belgian practitioners being married The receipts of garments, both for men and women, at 3, Hyde Park street, London, W (Dr Philippe s house, kindly lent for the purpose), have been satisfactory, and the hours of distribution have been arranged as follows Wednesday, 10 A.M to 12 noon for men, and Friday between the same hours for women

The case of surgical instruments designed for Belgium, and reported last week as being at the Tunnel Wharf, Rotherhithe, has been forwarded to Brussels, *viâ* Rotterdam, in the S S *Vesuvie*, which sailed on Feb 1st

THE MANCHESTER COMMITTEE

An important committee has been formed at Manchester, and a circular is on the point of being issued to the local members of the medical and pharmaceutical professions setting out the position of their Belgian colleagues The circular is signed by Dr Alfred Brown, President, Manchester Pathological Society, Mr J Gray Clegg, President, Manchester Clinical Society, Dr Archibald Donald, President, Manchester Medical Society, Mr James Grier, President, Manchester Pharmaceutical Association, Dr T Arthur Helme, President Manchester Medico Ethical Society, and the following members of the central committee Sir William Milligan, Professor G Elliot Smith, and Mr William Thorburn Dr E M Brockbank, Northern Assurance Buildings, Albert square, Manchester, and Mr Tom Miller, pharmacist, 5, Yarburgh street, Whalley Range, are acting as honorary secretaries

Subscriptions may be sent to either of the secretaries, who will acknowledge their receipt and pass them on to the Central Fund They will also be acknowledged in the medical and pharmaceutical papers Cheques should be crossed "Lancashire and Yorkshire Bank, Limited"

Contributions of surgical instruments likely to be of use to the Belgian doctors may be sent to the Library of the Medical Society, University of Manchester, where they will be sorted and sent on to London

The Manchester Committee propose also to appeal to the public through the lay papers

THE FUND OF THE LIVERPOOL MEDICAL INSTITUTION

The following is the second list of subscriptions which have been collected by the Liverpool Medical Institution —

	£	s	d.
Dr G A Crace-Calvert	5	5	0
Dr John E Gemmell	5	5	0

The Liverpool Belgian Doctors' Relief Fund is intended for the relief of Belgian doctors, and we are informed that the Liverpool Chemists' Association is forming a local fund for the relief of their professional colleagues The money in the hands of the Liverpool Medical Institution amounted on Feb 4th to £382 10*s* 3*d* The Fund is still open, and subscriptions should be sent to Dr T R Bradshaw, at the Institution, 65, Rodney street, Liverpool

THE DURHAM AND NEWCASTLE DISTRICT

Dr A S Percival, 17, Claremont place, Newcastle on Tyne, who is acting as one of the joint secretaries of the movement in this district, has written to the constituency in the following terms —

"We are under a lasting obligation to Belgium for her magnificent stand against the German invaders, indeed, it is an obligation that can never be fully repaid, and it should be regarded as a privilege to have this opportunity of showing our sympathy with our fellow practitioners Chiefly with this end in view a meeting will be held at the College of Medicine, Newcastle upon Tyne, on Wednesday next, Feb 17th, at 4 P M An address will be given by Professor Jacobs of Brussels, who will give evidence of certain startling facts that for ruthless and savage barbarity have no equal All doctors and pharmacists are invited to attend the meeting, at which it is proposed to form a committee for dealing with Belgium s appeal Meantime, any subscriptions that are sent to me in aid of the Fund will be gratefully acknowledged and duly reported in the medical journals '

THE WEEK S SUBSCRIPTIONS

The subscriptions received by Dr Des Vœux up to Tuesday evening last, in addition to those previously acknowledged, amounting to £5000, and not including money received by the Scottish or Irish Funds, are as follows —

	£	s	d.
Mr W Thomson Walker	5	5	0
Brussels Medical Graduates Association (per Dr Major Greenwood Treas) third donation	2	2	0
Dr Lauriston Shaw	5	5	0
Miss Lilian T Powland M B	2	2	0
Professor J A Kynoch	2	2	0
British Milk Products Company	73	19	9
Dr J Duncan Kendry	1	1	0
Dr Borra (per Dr Larking)	1	0	0
Oldham Medical Society collected by (per Dr F L Pochin)— Oldham Medical Society	10	10	0
Dr Lawrie	6	0	0
Dr Robertson	5	0	0
Dr J Fort	3	3	0
Dr W White	3	3	0
Dr Olive Claydon	3	0	0
Dr Cammock	2	2	0
Dr Fawsitt	2	2	0
Dr Henderson	2	2	0
Dr Hutton	2	2	0
Dr Kinnear	2	2	0
Dr Yates	2	2	0
Dr H J Gill	2	0	0
Dr Anderson	1	1	0
Dr Corns	1	1	0
Dr Doble	1	1	0
Dr Fulton	1	1	0
Dr Godson	1	1	0
Dr Heap	1	1	6

be afforded, including the provision of such artificial dentures as may be considered necessary for efficient mastication The existing limit of one pound (£1) per man may be exceeded in cases where the work necessitates a higher expenditure, provided that in no case is the expenditure to exceed three pounds (£3) per soldier treated without the special authority of the general officer commanding in chief Where available dentists attached to military hospitals will be employed to the fullest extent. For the supply of artificial dentures the following scale of fees is given as a guide to the maximum cost, having regard to the class of work required (*a*) Complete upper or lower denture from £2 to £3, (*b*) complete upper and lower dentures from £4 to £6, (*c*) partial upper or lower denture, comprising not more than five teeth, about £1 10*s*, or possibly a little higher.

EDINBURGH IN WAR TIME —Our Edinburgh correspondent writes "The Committee of Management of the Triple Qualification of the Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow have announced to students who have undertaken approved service with His Majesty's Forces that applications for partial recognition of such work in lieu of curriculum will be individually considered. Steps will be taken in each case to grant such concessions as appear to the committee to be in accordance with the recommendations of the General Medical Council —Twenty-nine convalescent sailors from the hospital at South Queensferry most of whom had been wounded in the recent North Sea fight, were removed on Feb 3rd by ambulance train to the Marchioness of Bute s auxiliary hospital at Mount Stuart in the Island of Bute. At Gourock the men were embarked on the Caledonian Company s steamer the *Duchess of Bute* Two ambulance wagons were supplied by the Red Cross Society in Edinburgh, and taken by train and boat to Rothesay for the comfortable conveyance of the seamen to Mount Stuart House. Meals were provided *en route* cooks being provided on the train by the Red Cross Society After an appreciable interval which presumably reflected in some degree the comparatively quiet spell at the front, another hospital train arrived in Edinburgh on the night of Feb 5th, bearing its burden of 100 wounded soldiers The wounded were received at the Caledonian Station by the Red Cross workers with their usual equipment of motor ambulances and motor-cars and were conveyed to Dalmeny House and the Deaconess Hospital."

A NEW ARMY HUT —Mr H A. Pritchard, A R I B A of Cardiff has designed a hut for the accommodation of soldiers which is now on view at the College of Ambulance, 3 Vere street, London W It is built of wood of standardised lengths and can therefore be turned out from the saw mill ready for erection The outside of the hut is covered with a durable waterproof material which ensures dryness and warmth and in hot weather would prevent the scorching heat attendant upon corrugated iron The whole appearance of the hut is like the roof of a dwelling house, the sides of the roof reaching almost to the ground whilst at the gable ends are the door and windows at one side and a large window at the other The hut measures 22 ft long, 14 ft wide and the highest point of the sloping roof is 15 ft from the ground The whole hut is raised from the ground some 12 in on concrete blocks so that there is ample ventilation beneath the oak flooring The hut can accommodate 14 men or as many as 16 at an emergency The ventilation is free and the light ample The whole hut is collapsible and can thus be easily transferred by road or rail and can therefore be used by an army on the march as part of its equipment for offices sleeping accommodation or for a temporary hospital. The free space in the centre affords room for men to use the hut as a bed sitting room. The cost of the hut completed is about £100 There are many ingenious devices which add to the benefits of the hut Before the door is a door mat' consisting of a wooden grill on which the men can get rid of the mud from their boots which renders huts of this kind like quagmires as a rule. To the upright poles in the hut a movable table is attached, which can be used for a mess table or an operating table if the hut is used as a hospital. Special arrangements for storing utensils, food, &c, are in evidence above the level of the men s heads Outside at either end of the hut where the roof slopes to the eaves a wide gutter trough receives the water from the roof and from which the water can be run off, or the whole trough can be lifted, placed on supports, and used for washing purposes by a number of men at a time. Instead of the water being allowed to run down to the eaves and the trough, it can be diverted by placing a wooden rod obliquely across the sloping roof, whereby the water is made to issue at one side of the roof a few feet above the ground where it can be collected in basins pails, &c., for future use Mr Pritchard s device seems not only ingenious but eminently useful for practical purposes, and the favourable comments passed upon the hut by officials and visitors on Saturday, Feb 6th, when the hut was inspected at the College of Ambulance, promise well for its success.

AMERICAN WOMEN'S WAR HOSPITAL.—The American Women's War Hospital at Paignton is being enlarged by 30 beds bringing the total capacity of the hospital up to 230 This addition has been made possible by utilising the fine Riding School. The new ward will be called "St. George' Ward after a generous donator to the fund and when completed will be staffed by English and American nurses, as are all the other wards in the hospital

A RECORD OF ATROCITY —In the *Field* this week Dr Arthur Tacquin, physician in ordinary to the King of the Belgians, tells the story of German cruelty, insolence, pillage, and arson exactly as it came under his own eye, with photographs taken by himself. The proclamations which the enemy has scattered through Belgium are many of them given in full in a terrible supplement to the great sporting newspaper and the editorial summary which introduces the startling pictures and text is a red hot indictment of German crime written in convincing terms

Medical News.

UNIVERSITY OF DURHAM (COLLEGE OF MEDICINE), NEWCASTLE-ON-TYNE.—At the annual meeting of the Council of this College held on Feb 9th an illuminated address, in Latin, was presented to Professor Sir G H. Philipson M D, the President of the College, congratulating him on the completion of his 50 years service to the College. The address called attention in the following terms to his varied and eminent services "Quis enim nostrum ignorat te pathologiae doctrinam, medendi scientiam atque usum, epistularum academicarum commercium totius denique Collegii regimen, pari deinceps cum diligentia et humanitate curavisse'"

DONATIONS AND BEQUESTS —By the will of the late Mr William Long, of Gloucester, the testator has left £10 000 to the Gloucester District Nursing Society and £3000 to the Gloucester Provident Dispensary —The late Mr William Ransom, of Hitchin, has bequeathed £500 to the North Herts and South Beds Hospital —The late Major W Barrett of Moredon, Somerset has left by will £1000 to the Taunton and Somerset Hospital for the endowment of a bed.

BADGE FOR THE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF IRELAND —At the last meeting of the Royal College of Physicians of Ireland the ex President, Dr C E FitzGerald asked permission to present to the college an official badge to be worn by the President on ceremonial occasions He wished to commemorate the fact that in his person the college had for the first time elected an ophthalmologist to its highest office The college gratefully received the gift

MEDICAL MAGISTRATE —Dr William Dunn has been made a Commissioner of the Peace for the county of Rutland.

Dr Stanley Riseley, until recently ophthalmic surgeon to the Royal Hospital, Sheffield, has died at the early age of 47 extended to include vulnerable places on the coast The committee of the Royal Society of Medicine, which has been occupied with the medical side of the matter, has now organised a service of surgeons, anæsthetists, and dressers, ready to proceed at once in self contained units to any point where their services are required, travelling either by motor car or by special train according to the needs of the occasion.

THE DISLOCATION OF MEDICAL SERVICE

A meeting of medical practitioners and senior students was held in the Royal College of Surgeons, Edinburgh, on Monday last, when Mr Hodsdon, President of the College and chairman of the meeting, spoke forcibly on the situation of civilian practitioners Many civil practitioners, he said, had attached themselves to various units, and were willing to spend their spare time in military duties, but they were not prepared and did not anticipate that they would be called away from their practice at a moment's notice At that moment there were men who had not been back to their practice since they were called up during the mobilisation in August The Scottish Medical Service Emergency Committee had assisted medical men who were with the colours, while at the instance of the General Medical Council the War Office had now made exchanges possible whereby the Scottish practitioner might find himself back in his own town

Dr Norman Walker, convener of the Scottish Medical Service Emergency Committee, said that the work of the committee had extended far beyond that of merely introducing assistants or locum tenents to men who wanted them The dislocation of medical practice in the country had increased, and was still increasing, and if they were to avoid a serious breakdown in the medical service in Scotland they must realise the situation, for more demands would be made upon them, and the supplies would have to be very carefully husbanded if they were to meet that demand They had to supply recruits for two armies—one the King's forces, and the other the standing army for home defence against the constant enemies, disease and death It was because doctors were as necessary in the army and navy as engineers, gunners, and air men that it was incumbent on the medical profession to supply the wants of the King's forces Something over one sixth of the medical profession were already serving—nearly 7000 out of a total of 37,000—and more were required, for the day was not far distant when six figures would not cover the number of our forces abroad Seeking where the additional doctors were to come from, Dr Norman Walker hoped no licensing body, from a sort of morbid patriotism, would admit to the profession insufficiently trained students The student's business was to work hard, and the teacher's to give more care to his teaching than he ever gave before, so that the student should complete his course in the shortest possible time and then offer his services to the country if there were no valid reason against this course But if such reason existed it must be remembered that a man still served his country if, by undertaking the work of one who had gone, he so loyally respected his interests that the other went with an easy mind But the country districts were crying out for doctors and before many weeks passed they would be very near the Trade Unionist Paradise—"two jobs for every man Dr Norman Walker concluded by referring to the new Army Order permitting exchanges, and begged that it should be taken advantage of by medical men.

Principal Sir Donald MacAlister acknowledged how cordially, as soon as it understood the difficulty they were in as regards civil practice, the Army Medical Service responded in the only way they were able to respond. It was quite clear that the civil service must dispense with its ordinary superabundance of practitioners if the army was to be supplied, and the question was whether a proper reorganisation of the civil service could be achieved For the first two or three months it looked as if it could be done without much difficulty, but difficulties that seemed at first not impossible were becoming almost impossible to overcome, and it was quite certain that the civil community would have to do with a good deal less doctoring if they were to keep the army supplied, as it ought to be supplied, with doctors They had better face the situation now, he urged, before in some areas the medical service altogether broke down He believed that by a redistribution of their forces there could be provided a respectable medical service for all the civil population, but the worst of it was that while there was a superabundance in some places there was a very deficient service in others He did not see any other machinery in existence for attempting the difficult problem of organising a redistribution than the Emergency Committee A certain number of Belgians would be available, and the reciprocal privilege of practising in Belgium after the war would be no small one He believed there were also coming to this country about 100 Canadian registered surgeons and a certain number from Australia and India

The gist of an important meeting was to show that the shortage of medical men is expected in the best informed circles to become more serious

UNIVERSITY OF LONDON SPECIAL LECTURES IN MILITARY HYGIENE —With the concurrence and assistance of the Army Council a course of nine lectures on "The Health of the Army in the Field" will be given at the Royal Army Medical College, Millbank S W, by Major P S Lelean R A M C, F R C S, D P H, at 5 P M, on Feb 22nd 24th, and 25th, and March 1st 3rd 5th 8th, 10th, and 12th The course will form an introduction to the problems of hygiene of forces in the field for (i) qualified medical men without military experience, (ii) combatant officers about to proceed to the front, and (iii) others interested in the subject (provided the accommodation is sufficient) In the allocation of tickets preference will be given in this order A detailed syllabus will be available for the lectures, at which the following matters will be dealt with hygiene of active service, sickness in the army organisation and administration in the field, water and water supplies and conservancy on active service Arrangements will be made if desired, for visits of inspection to a typical camp Applications for tickets should be made to the Academic Registrar University of London, South Kensington S W, and be accompanied by remittance of the fee of £1 1s Applicants should indicate whether the tickets are required for (1) medical men, (2) combatant officers proceeding to the front, or (3) other persons Tickets will not be despatched before Feb 15th.

DENTAL AID FOR THE TROOPS —A circular letter was issued by the War Office to the various commands on Jan 22nd with reference to the subject of dental aid for the troops In this it is announced that as a temporary measure for the period of the present war only the existing system whereby a sum of money is allotted to each command for the dental treatment of recruits and serving soldiers will be held in abeyance During the war all dental treatment necessary to render a non-commissioned officer or man fit for service in the field will in the course of his observations, said I should not like to conclude without saying a few words upon certain aspects of the medical treatment of the wounded in France I do not think there is much that I can add to the narrative which I gave to the House in November last of the methods adopted by the Royal Army Medical Corps in bringing the wounded from the front to the clearing stations, thence to the base hospitals, and finally home here Important as those functions are, the prevention of disease is even more important and that is rightly regarded as the primary function of this corps I think that I am right in saying that this is the first war in which we have been engaged in which an organised sanitary service has existed We owe the establishment of this service to my noble friend Lord Haldane Since its establishment we have been gradually perfecting its organisation during the last five or six years When we look back to the fact that during the Napoleonic wars only 3 per cent of deaths among our troops were due to wounds and 97 per cent due to sickness or disease, and when we also remember the fact that during the Crimean War more deaths occurred from disease during the first three months than during the whole of the rest of the campaign, it is impossible to lay too much stress upon this preventive function of the Royal Army Medical Corps How has this function been carried out? I have to thank my honourable friend the Member for the Holmfirth Division of Yorkshire (Mr Arnold) for the very interesting and able report which he made to me after a visit which he paid to Paris, during which he got a great many figures. All the evidence which my honourable friend brought and which comes to me officially, goes to show that by far the greatest amount of sickness amongst our soldiers at the present moment is due to the wet and the cold Frost-bite and rheumatism are I am sorry to say, very prevalent We have issued from the War Office through the Army Medical Department a small leaflet to officers and non-commissioned officers telling them how to prevent frost-bite amongst their men My honourable friend reports to me that, assuming the conditions of exposure of officers and men to be identical, frost-bite is three times as prevalent amongst the men as it is amongst the officers I do not suppose that it is possible to assume that the conditions are quite identical but you may be certain that the exposure of the men is not three times as great as that of the officers My honourable friend presumes that this result is due to the officers having better boots, leggings, and equipment generally If that is so it proves that there is a certain amount of preventability of frost-bite, and I hope by the steps which we are now taking that this disease may be prevented to a larger extent than has been the case in the past

The Question of Compulsory Inoculation

Coming now to the question of enteric fever (continued the right honourable gentleman) I am glad to say that cases of this disease are luckily rare, and they have occurred almost entirely among the uninoculated The evidence is accumulating in favour of making inoculation compulsory This is one of those subjects which ought to be settled without prejudice My honourable friend the Member for Holmfirth who gave me this most interesting report, strongly holds that inoculation against typhoid ought to be made compulsory It is for the House to say what they think upon this matter I gave the House figures to-day on this subject in answer to a question and they have been published in a leaflet to all soldiers with a prefatory note by the Secretary of State for War (Lord Kitchener) impressing upon all soldiers the great importance of inoculation

Lord CHARLES BERESFORD Does every soldier get one?

Mr TENNANT Yes it is sent to every soldier

Lord CHARLES BERESFORD Is it put up in the recruiting offices?

Mr TENNANT Very likely I have not time to go in detail into all the preventive measures taken by the Royal Army Medical Corps but I should like to mention the sanitary squads the water purifying sections, and the travelling hygiene and bacteriological laboratories to which I drew attention in my speech in November This is an entirely new feature and these branches in particular are doing extraordinary and valuable work Lastly, the Sanitary Commission sits at the War Office to advise the Secretary of State upon all matters relating to the health of the troops at home and abroad What I have said relates to the army abroad, and it may be asked what we are doing for the health of our troops at home Owing to the almost entire absence of the regular Army Medical Service engaged upon field operations certain difficulties have arisen, but thanks to the patriotic eagerness of the medical profession we have been able to obtain a high degree of efficiency I cannot claim that complete efficiency has been achieved but day by day the ideal is being approached The new Army Medical Corps for the new armies are now in course of formation and I believe they will be able to do excellent work should the occasion arise

Vaccination of Soldiers

Mr TENNANT informed Mr THOMAS that it was not considered advisable to alter the present rules governing the vaccination of soldiers joining the army

Territorial Medical Officers

In reply to Mr W GUINNESS, Mr BAKER (Financial Secretary to the War Office) said There is no difference in the pay of officers holding temporary and permanent commissions in the Royal Army Medical Corps, Territorial Force The rate for captain is 15*s* 6*d* and for lieutenant 14*s* a day

Antityphoid Inoculation in Canadian Contingent

Mr TENNANT informed Mr PETO that 95 per cent of all ranks of the Canadian Contingent had been inoculated against typhoid

The Anti inoculation Campaign

Sir J D REES asked the Attorney General whether the Government could and would proceed under the Defence of the Realm Act against persons who incite soldiers to decline to submit to antityphoid inoculation —Sir JOHN SIMON replied The matter is under the consideration of the military authorities

Inoculation of Soldiers against Typhoid Fever

In the course of the debate in committee of supply on army estimates Mr CHANCELLOR drew attention to the inoculation of troops He said that assurances had been given in Parliament by representatives of the War Office that no compulsion should be applied to soldiers to compel them to undergo inoculation. Those assurances had not been reflected in certain instances in the action which had been taken by officers They had, by depriving men of privileges and in other ways, sought to coerce them to submit to this operation against their wishes He did not complain about the inoculation of troops, nor did he complain of proper and legitimate methods of persuasion But he did object most strongly to the coercion and compulsion which had been applied to men who had conscientious objections, and he hoped that officers who exerted compulsion and coercion would be reprimanded The man had a right to refuse to be inoculated

Mr G H ROBERTS stated that he had taken part in the recruiting meetings, and he had told men on certain occasions that the Government had given an assurance that inoculation was not compulsory If it was made compulsory these men should have an opportunity to retire

Sir HENRY CRAIK protested against the campaign which had been carried on against the inoculation of troops Inoculation was carried out in the general interest of the health of the troops

Dr C ADDISON (Parliamentary Secretary to the Board of Education) said that he had been asked by the Under Secretary for War to deal with the question of inoculation Was this thing desirable in itself? Would it prevent the occurrence of typhoid fever amongst our troops abroad to a material extent? Would it reduce the strain on our men? That was the big question Where inoculations were carried out with care the number of cases who did badly was infinitesimal Even if a man did die in a particularly vulnerable moment, that would not prove that this was not a preventive against typhoid. We had a great force on the continent of Europe, greater than we ever had before, and after six months, including three months of the most atrocious weather imaginable, there had only been 421 cases of the disease The fact that the figures were so small was a vindication of the policy of inoculation It seemed strange how the disease had picked out the uninoculated men in a very careful way The more the records of this remedy of inoculation were examined the better did it appear It was never contended that there were no men who were inoculated who would not suffer from typhoid In time the remedy might be so perfected that it might become absolutely perfect He was not contending that it had proved perfect now The point was this Was it so much of a protection that it diminished disease in our troops abroad that it was worth doing? There had been 58,000 cases of enteric in the South African War Up to the present in this war there had been 421 Whatever this was due to, it had at least happened and let them continue this happy conjunction of affairs and hope that it would continue to happen It was said that a good many men might have their consciences hurt by compulsion Many people, however had made it their business to go about spreading leaflets "Is it patriotic to oppose the vaccination and inoculation of our soldiers?" That question was asked at the top of one of these leaflets And the answer given was "Certainly it is." That was a campaign against antityphoid inoculation but it was not against personal rights. After all, there might be in different parts of the country excess of enthusiasm on the part of officers who sincerely believed that the troops which they were now commanding would be safer inoculated than not If an officer was taking a battalion out to the

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

The Parliamentary Session

PARLIAMENT is again in session, and it is expected to sit continuously for four or five weeks All its attention is being given to problems arising out of the war Matters of party controversy are not being dealt with

The Inoculation of British Troops

Very considerable attention has been given in the House of Commons within the past few days to the subject of the inoculation of British troops against typhoid There are three distinct sets of opinion on the subject A very large body of members think that all future recruits who join the army should do so on the express condition that they should undergo inoculation, and that all soldiers who are already in the ranks and refuse to submit to the operation should either be allowed to retire or be allocated to home defence work No uninoculated men should go to the front The second set of opinion is that the present system of voluntary inoculation should continue, but that every means of persuasion short of coercion should be exerted to induce men to be inoculated This view admits the value of the operation, but would leave an option with the individual The third set of opinion is that of the anti inoculation party, which is very small numerically Its activities have been directed to drawing attention to cases in which it alleges illegitimate pressure has been exerted on soldiers to coerce them into undergoing inoculation In these circumstances it is most important to watch the attitude of the Government and of the War Office Mr TENNANT, the Under Secretary for War stated in the House of Commons this week that the evidence was accumulating in favour of the inoculation of our troops The matter of making it compulsory was under consideration, and he hoped to be able to give a definite answer shortly Some highly significant statistics showing the beneficial effect of inoculation against typhoid in the present war have been given to Parliament in the course of the last few days

HOUSE OF COMMONS

THURSDAY, FEB 4TH

Treatment of Mental Strain amongst Soldiers

Mr DUNCAN MILLAR asked the Under Secretary for War whether steps had been taken to secure that the treatment of soldiers and sailors suffering from mental strain should be carried out in hospital wards or other institutions not under lunacy administration, so as to avoid sending all such cases, which were not certifiable, to asylums —Mr TENNANT replied Every endeavour is being made to treat patients suffering from traumatic neurasthenia and cases of mental strain in such a manner as to avoid sending those not certifiable into asylums For this purpose arrangements have been made to treat such cases in certain private and civil hospitals in the United Kingdom, and a Red Cross Military Hospital has been opened in Lancashire for their reception This latter hospital is administered by and the patients are under the care of medical officers holding commissions in the Royal Army Medical Corps

Mr DUNCAN MILLAR Is the War Office prepared to make a grant for equipment?—Mr TENNANT I do not think so

Inoculation against Enteric Fever

Mr LAURENCE HARDY asked the Under Secretary for War whether he was aware of the campaign which was in existence for the purpose of discouraging our soldiers in the new armies from being inoculated against enteric and other similar diseases, whether, in view of the statistics in support of inoculation as shown during the present war, measures would be at once taken against any organisation which carried on such an agitation, and whether he would consider whether the time had now come when inoculation should be made compulsory for all soldiers proceeding to the front on active service, both for their own sakes and those with whom they were in contact

Mr PETO also asked the right honourable gentleman whether inoculation against typhoid fever and vaccination against small pox would in future be compulsory for all ranks in the military forces of the Crown before they were sent on service over sea during the currency of the present war —Mr TENNANT (replying to both questions) said The answer to the first point in the question of the honourable Member for Ashford (Mr L Hardy) is in the affirmative and to the second is that it is not proposed to take any action against the organisations referred to As regards compulsion I am advised that legislation would be necessary The introduction of a Bill is not at present contemplated, though this may be further considered should necessity arise

Pay of Medical Officers in the Territorial Force

Mr STEWART asked the Financial Secretary to the War Office whether medical officers in the new army were paid £1 4s a day, whereas medical officers who had served for years in the Territorial Force, and who had now volunteered for service anywhere, received only 15s 6d a day, and whether he could see a way to remedy the grievance of the Territorial service by putting them on the same scale of pay as the surgeons in the new army —Mr H BAKER I would refer the honourable Member to the answer which I gave to the honourable Member for the Bridgwater Division of Somerset on August 27th last[1]

Pay of Indian Medical Service Officers on Active Service

Mr RAWLINSON asked the Under Secretary for India whether his attention had been called to the reduced rate of pay of doctor of medicine officers of the Indian Medical Service who were now on active service with field ambulances, and whether he could see his way to raising their pay to the amount which they would receive if they were working for the Indian Medical Service in India during times of peace —Mr C ROBERTS wrote in reply Subject to certain exceptions which are at present under discussion with the Government of India, officers of the Indian Medical Service withdrawn from their ordinary duty for active service receive not less than the military pay and allowances ordinarily attached to their rank and position, and in some cases special higher rates provided for field service appointments The Secretary of State recognises that the rules may sometimes entail loss of emoluments to Indian Medical Service officers withdrawn from civil appointments but liability to recall to military duty is a well understood condition of civil employment in the case of the Indian Medical Service, and he sees no sufficient reason for modifying the rules

MONDAY, FEB 8TH

Antityphoid Inoculation in the British Army

Mr PETO asked the Under Secretary for War whether he could furnish particulars of any case of death from inoculation against typhoid fever —Mr TENNANT replied So far as the War Office is aware there has been only one death which can be in any way connected with inoculation This case was that of Corporal Nichols, of the 3rd Battalion (Reserve) City of London Regiment I stated in this House on Nov 27th last that the cause of death was pneumonia but when the death certificate was received it was seen that the cause was given as (1) antityphoid vaccination and (2) pneumonia The case has been investigated and submitted to Sir William Osler, who considers that death was due to an eight miles march which the man took within 24 hours after inoculation and not to the inoculation directly Instructions have been given that care must be taken to see that men recently inoculated are not given hard work until their condition justifies their undertaking it without risk

Mr PETO asked the Under Secretary for War whether he could state the number of cases of typhoid and deaths from typhoid, among inoculated men and uninoculated men in the Expeditionary Force from the commencement of the war to a recent date —Mr TENNANT answered Of the 421 cases of typhoid in the present campaign among British troops 305 cases were in men who were not inoculated within two years In the 421 cases there have been 36 deaths Of these deaths 34 were men who had not been inoculated within two years Only one death occurred among patients who were inoculated, and that man had only been inoculated once instead of the proper number of times —namely, twice

Mr CHANCELLOR asked the right honourable gentleman whether the punishment for refusing inoculation of men who had fought at the front by depriving them of the five days' leave to visit home which was granted to inoculated men was a form of influence and persuasion sanctioned by the War Office to induce men to undergo an operation which was not compulsory or legally enforceable and to which they had a conscientious objection and whether men who stood upon the legal right guaranteed by the public announcements of the Minister for War were to be punished indefinitely for doing so by the refusal of the leave granted to others or whether this action on the part of officers would at once be put an end to by a General Order issued from the War Office —Mr TENNANT said in reply I am not aware of any case where a man returning from the front has been punished in the manner described in the question The danger of infection being spread in the army by uninoculated men is considerable and has to be guarded against by precautions being taken as regards granting them special leave Any General Order will be in this sense

The Health of the Army

Speaking on the motion that the Speaker should leave the chair in order that the House might go into committee on army estimates Mr TENNANT (Under Secretary for War),

---

[1] THE LANCET Sept 5th 1914 p 677

Colchester, Royal Eastern Counties Institution for Imbeciles and the Feeble Minded.—Medical Officer. Salary at rate of £200 per annum, with board, apartments, attendance, and washing.

Coventry, Coventry and Warwickshire Hospital.—House Physician. Salary £110 per annum, with rooms, board, washing, and attendance.

Dagenham Temporary Sanatorium, Dagenham, Essex.—Resident Medical Officer, unmarried. Salary at rate of £500 per annum and all found.

Derbyshire County Council.—Tuberculosis Dispensary Officers. Salary £[illegible]0 per annum.

Devizes, Wilts County Asylum.—Assistant Medical Officer. Salary £250 per annum, with apartments, board, attendance, and laundry.

Devonport, Royal Albert Hospital.—House Surgeon, unmarried. Salary £150 per annum, with board and laundry.

Dudley, Guest Hospital.—Senior Resident Medical Officer. Also Assistant House Surgeon for six months. Salary £150 and £120 per annum respectively, with board, residence, attendance, and washing.

Dumfries and Galloway Royal Infirmary.—Female Resident House Surgeon. Salary £100 per annum.

Eccles and Patricroft Hospital.—House Surgeon, unmarried. Salary £70 per annum, with board, lodging, and washing.

Exeter, Royal Devon and Exeter Hospital.—Senior House Surgeon for 12 months. Also House Physician and Assistant House Surgeon for six months. Salary at rate of £250 per annum for senior post and £150 for junior posts, with board, apartments, and washing.

Glamorgan County Council.—Medical Officer for Inspection of Children in Public Elementary Schools. Salary at rate of £300 per annum.

Glasgow Royal Samaritan Hospital for Women.—Resident Medical Officer. Salary £25 per annum.

Government Lymph Establishment, Colindale-avenue, Hendon, N.W.—Temporary Assistant Bacteriologist. Salary at rate of £500 per annum.

Halifax Royal Infirmary.—Second and Third House Surgeons, unmarried. Salary £120 and £100 per annum respectively, with residence, board, and washing.

Hospital for Sick Children, Great Ormond-street, London, W.C.—Assistant Casualty Medical Officer, unmarried, for six months. Salary £50, with board, residence, &c.

Hull, Victoria Children's Hospital, Park-street.—House Surgeon and Assistant House Surgeon. Salary £60 and £50 per annum respectively, with board and laundry.

Kensington Tuberculosis Dispensary, 110, Ladbroke-grove, W.—Temporary Medical Officer. Salary at rate of £[illegible]00 per annum.

Laboratories of Pathology and Public Health.—Bacteriologist. Salary £170 per annum.

Lindsey (Lincolnshire) County Council.—Combined Temporary Assistant Tuberculosis and Assistant School Medical Officers. Salary at rate of £3[illegible]0 per annum.

Liverpool Infirmary for Children.—Two Resident House Physicians for six months. Salary £50 each, with board and lodging.

London Hospital, E.—Assistant Surgeon.

Manchester, County Asylum, Prestwich.—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, apartments, attendance, and washing.

Manchester, Monsall Fever Hospital.—Second and Third Medical Assistants. Salary £175 and £150 per annum respectively, with board, lodgings, and washing.

Manchester, Victoria Memorial Jewish Hospital, Cheetham.—Female Resident Medical Officer for six months. Salary at rate of £1[illegible]0 per annum, with rooms, board, and laundry.

Metropolitan Borough of Hackney and Stoke Newington.—Tuberculosis Officer. Salary at rate of £500 per annum.

Middlesex County Asylum, Napsbury, near St. Albans.—Temporary Assistant Medical Officer. Salary 6 guineas per week, with board, lodging, washing, and attendance.

Mile End Old Town Infirmary.—Senior Assistant Medical Officer and Junior Assistant Medical Officer. Salary £220 and £150 per annum respectively, with board, lodging, and washing.

Miller General Hospital for South-East London, Greenwich-road, S.E.—Junior House Surgeon for six months. Salary £[illegible]5 per annum, with board, residence, and laundry.

Newport (Mon.), Royal Gwent Hospital.—Resident Medical Officer. Salary for first six months at rate of £100 per annum, second six months £125, and third six months £150, with board, residence, and laundry.

Norfolk Education Committee.—Assistant Medical Officer. Salary £300 per annum.

Northampton County Asylum.—Second Assistant Medical Officer. Salary £250 per annum, with board, &c.

Nottingham General Hospital.—Senior House Physician. Salary £120 per annum, with board, residence, and laundry. Also Assistant House Physician for six months. Salary at rate of £100 per annum, with board, residence, and laundry.

Oldham Royal Infirmary.—Second House Surgeon. Salary at rate of £120 per annum, with board, residence, and laundry.

Paddington Green Children's Hospital, London, W.—House Surgeon. Salary at rate of £[illegible]0 per annum, with board, residence, and washing.

Paddington Infirmary, 225, Harrow-road, Paddington, W.—Two Assistants to Medical Superintendent of Infirmary and Medical Officer of Workhouse for six months. Salary at rate of £250 per annum, with board, lodging, and washing.

Paisley, Royal Alexandra Infirmary.—Resident House Physician.

Preston Royal Infirmary.—Assistant Resident Medical and Surgical Officer. Salary £120 per annum, with board, residence, and laundry.

Portsmouth, Royal Hospital.—House Surgeon for six months. Salary £[illegible] per annum, with board, &c.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Assistant Surgeon.

Rhondda Urban District Council.—Temporary Assistant Medical Officer of Health and School Medical Officer. Salary at rate of £[illegible] per annum.

Royal Army Medical Corps (Territorials), Third Home Counties Field Ambulance (Maidstone).—Seven Medical Men as Officers.

Royal Dental Hospital of London, Leicester-square.—Junior Assistant House Anæsthetist. Salary £[illegible] per annum.

Royal Waterloo Hospital for Children and Women, S.E.—Second Resident Medical Officer. Salary at rate of £100 per annum, with board and washing. Also Temporary Honorary Assistant Physician to Out-patients.

St. Mary's Hospital for Women and Children, Plaistow, E.—Junior Resident Medical Officer. Salary at rate of £90 per annum, with board, residence, and laundry.

St. Mary Islington Infirmary, Highgate Hill, N.—Junior Assistant Medical Officer. Salary £140 per annum, with board, residence, &c.

St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—Junior House Surgeon for six months. Salary at rate of £75 per annum, with board, lodging, and washing.

Salford County Borough.—Assistant Tuberculosis Officer. Salary £350 per annum.

Salford Royal Hospital.—Casualty House Surgeon. Salary at rate of £100 per annum, with board and residence.

Salisbury General Infirmary.—House Surgeon and Assistant House Surgeon, unmarried. Salary £100 and £75 per annum respectively, with apartments, board, lodging, and washing.

Sheffield Children's Hospital.—House Surgeon. Salary £150 per annum, with board and residence.

Sheffield City Hospitals for Infectious Diseases and Tuberculosis.—First Assistant Medical Officer, Second Assistant Medical Officer, and Third Assistant Medical Officer. Salary £250, £225, and £200 per annum respectively, with apartments, rations, laundry, and attendance.

Sheffield Royal Hospital.—Female Assistant House Surgeon and Assistant House Physician. Salary £85 and £80 per annum respectively, with board, residence, and washing.

Southampton, Royal South Hants and Southampton Hospital.—Junior House Surgeon for six months. Salary at rate of £120 per annum, with rooms, board, and washing.

South Shields, Ingham Infirmary and South Shields and Westoe Dispensary.—Junior House Surgeon. Salary £115 per annum, with residence, board, and washing.

Stockport Infirmary.—Junior House Surgeon. Salary £100 per annum, with board, washing, and residence.

Swansea Union Institution.—Resident Assistant Medical Officer. Salary £225 per annum.

Taunton and Somerset Hospital, Taunton.—Senior House Surgeon. Salary £120 per annum, with board, lodging, and laundry.

Truro, Royal Cornwall Infirmary.—House Surgeon, unmarried. Salary £150 per annum, with rooms, board, and washing.

Tunbridge Wells General Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board, residence, &c.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—House Physician for six months. Salary £[illegible]0, with board and lodging.

Wakefield, City of.—Temporary Assistant Medical Officer of Health. Salary £500 per annum.

Walsall and District Hospital.—Assistant House Surgeon and Anæsthetist. Salary £1[illegible]0 per annum, with board, residence, and laundry.

Wandsworth Union Infirmary, St. John's-hill, Clapham Junction, S.W.—Assistant Medical Officer, unmarried. Salary at rate of £5 5s. weekly, with board, lodging, and washing.

Warrington Infirmary and Dispensary.—Senior House Surgeon. Salary at rate of £200 per annum, with board, apartments, and laundry.

West Bromwich and District Hospital.—House Surgeon and Assistant House Surgeon, unmarried. Salary £150 and £120 per annum respectively, with residence, board, and laundry.

West End Hospital for Diseases of the Nervous System, Paralysis, and Epilepsy, 73, Welbeck-street, W.—Resident House Physician for six months. Salary at rate of £100 per annum.

West Ham and Eastern General Hospital, Stratford, E.—Junior House Surgeon. Salary at rate of £100 per annum, with board, residence, and washing.

Whitechapel Union Infirmary, Vallance-road, E.—Second Assistant Resident Medical Officer. Salary £200 per annum, with rations, apartments, and washing.

Wigan, Royal Albert Edward Infirmary and Dispensary.—Female Junior House Surgeon. Salary £130 per annum, with board, apartments, and washing. Also House Surgeon. Salary £170 per annum, with board, apartments, and washing.

The Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Lerwick, in the county of Shetland; at Newent, in the county of Gloucester; and at Stewartstown, in the county of Tyrone.

Births, Marriages, and Deaths.

BIRTHS

Bidwell.—On Feb. 4th, at Worthing-road, Southsea, the wife of Fleet-Surgeon Lawrence Bidwell, R.N., of a son.

Hayden.—On Feb. 4th, at Wymering-mansions, W., the wife of Captain A. F. Hayden, M.B., F.R.C.S., I.M.S. (ret.), of a son.

Jordan.—On Feb. 4th, at 13, Upper Wimpole-street, W., to Dr. and Mrs. Alfred C. Jordan, a son.

MARRIAGES

Cunningham—Neal.—On Feb. 2nd, at St. Augustine's, Highbury New Park, Frederick Hugh Lester Cunningham, M.R.C.S., L.R.C.P., R.N., to Marguerite [illegible], younger daughter of Mr. and Mrs. John Neal.

Hill—Trollope.—On Feb. [illegible], at All Saints, Banstead, Lieutenant F. T. Hill, R.A.M.C., to Ruth [illegible], elder daughter of Howard W. Trollope, of Banstead, Surrey.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

front, and if he believed that the burden of transport would be less and that the fighting units at the front would remain more intact because the men were inoculated, one could understand a little excessive zeal on his part in getting the men inoculated He hoped that honourable Members would not allow this grave question to be clouded over by trivialities Let them look at it as a whole What the Government were doing was designed to protect our men against this disease in France, and he was sure that every honourable Member would coöperate with the War Office in placing no undue obstacles in the way

Mr W LONG thanked the honourable gentleman (Dr Addison) for the stand he had taken on this important matter The Opposition would support the Government in taking the strongest measures in securing the health of our troops in France If the Government had given a pledge to recruits not to make inoculation compulsory, and if they thought a change of policy was required, then the change of policy should be made at once Any men who thought that they were aggrieved by making inoculation compulsory should be given an opportunity of retiring or of being retained for home defence

WEDNESDAY, FEB 10TH

Inoculation in the British Army

In the further course of the debate in Committee of Supply on Army Estimates, Mr TENNANT (Under Secretary for War) said that evidence was accumulating in favour of the inoculation of our troops against typhoid In the South African War out of 21,000 deaths, 8000 were from enteric fever The Indian figures also were significant In India, where the troops ran great risk of disease, over 90 per cent of the army were without compulsion inoculated In pre inoculation days up to 2000 cases of typhoid used to occur annually in India, whereas in 1912 the number was only 118 and in 1913 only 85 As to making inoculation compulsory for future recruits and allowing those who had enlisted under the supposed guarantee of the War Office liberty to remain in the army for home defence only, he could give no answer The matter was under consideration, and he hoped to be able to give a definite answer shortly The question between the honourable Member for Haggerston (Mr Chancellor) and himself seemed to be not so much one of medical authority as one of discipline It was said that whilst it was stated that inoculation was voluntary in fact, a soldier desiring to remain uninoculated was met by the commanding officers of certain units with a form of compulsion which it was almost impossible to resist It would be almost impossible to persuade the honourable Member that these commanding officers had acted with the best possible motives, believing that the course adopted by the individual was likely to be prejudicial to the great bulk of the men under his command That was really the whole point These commanding officers had gone beyond any leave which they had from the War Office He had caused instructions to be issued to all commanding officers to say that action such as the honourable Member (Mr Chancellor) had brought to his notice was undesirable, and would, he hoped, not be repeated He (Mr Tennant) did not disguise that he felt that there was a real danger in men going on leave uninoculated and returning uninoculated, because they might bring infection to a body of troops Lord Kitchener felt this so strongly that he was about to issue instructions that leave must be sparingly granted to men who declined to be inoculated

Appointments.

Successful applicants for vacancies Secretaries of Public Institutions and others possessing information suitable for this column are invited to forward to THE LANCET *Office directed to the Sub-Editor not later than 9 o'clock on the Thursday morning of each week such information for gratuitous publication*

BIRD G A M B, B S B Sc. Lond has been appointed Casualty Officer and Resident Anæsthetist at St Thomas's Hospital

BLUNT A L M R C S L R C P Lond has been appointed Resident House Surgeon at St Thomas's Hospital

BOWSER G A G M R C S L R C P Lond has been appointed Casualty Officer and Resident Anæsthetist at St Thomas's Hospital

BURT W M R C S L R C P Lond has been appointed Senior Obstetric House Physician at St Thomas's Hospital

CRANSTON G M R C S L R C P Lond., has been appointed Resident House Physician at St Thomas's Hospital

DAVIES J C M B B Ch Oxon has been appointed Casualty Officer and Resident Anæsthetist at St Thomas's Hospital.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters whether intended for insertion or for private information must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor"

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index and Title-page to Vol. II. of 1914 were given in THE LANCET of Dec. 26th, 1914

VOLUMES AND CASES

VOLUMES for the second half of the year 1914 are now ready Bound in cloth, gilt lettered, price 16*s*, carriage extra.

Cases for binding the half year s numbers are also ready Cloth, gilt lettered, price 2*s*, by post 2*s* 3*d*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows —

FOR THE UNITED KINGDOM.			
One Year	£1	1	0
Six Months	0	12	6
Three Months	0	6	6

TO THE COLONIES AND ABROAD			
One Year	£1	5	0
Six Months	0	14	0
Three Months	0	7	0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

TO COLONIAL AND FOREIGN SUBSCRIBERS

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO , 51, Fifth Avenue, New York, U S A.

Notes, Short Comments, and Answers to Correspondents.

DANGEROUS FADS

To the Editor of THE LANCET

SIR,—I was really taken aback at seeing in one of the *recent numbers of Punch* the advertisement of a baseless campaign that is being waged against vaccines in general and antityphoid in particular

To us who hold England up as an *example, it is hard to* realise that there should still exist in a civilised country like yours people ignorant enough to publish and sustain the senseless principles contained in the aforesaid advertisement And what I think makes that calumnious campaign still worse, under the present circumstances, is the anti patriotic terms in which it is written

I think it is abopt time English people woke up against many such dangerous fads as have been taking root during recent years, such as this one, the antivivisection, and even vegetarianism, and the abuse of other diet fads Let us hope now that there are more serious things to turn one's thoughts to people will give up brooding over such nonsensical stuff

I am, Sir, yours faithfully,

Oviedo, Feb 3rd, 1915 JAMES B VILIESID

ANTIFORMIN

MR Walter J Matthews, of the laboratory department at the Bristol Municipal *Tuberculosis Dispensaries,* points out that a *perfectly efficient substitute for antiformin* hitherto supplied from Germany may be made by passing chlorine into 15 per cent sodium hydrate to nearly saturation The chlorine may be prepared by adding *pure hydrochloric acid to manganese dioxide* To make one litre 1 lb of *pure acid (specific gravity* 1 16) and about 6 oz of manganese dioxide are needed The manganese dioxide is placed in a large flask and the acid gradually added through a thistle funnel, warming very *gently The chlorine is carried by a delivery tube to the bottom of the soda solution,* which is placed in a tall bottle Enough chlorine has been added when the soda solution acquires the colour of lemonade The cost of making one litre works out, on Mr Matthews's estimate, at about 1*s* 1*d* Antiformin is used in the bacteriological diagnosis of tuberculosis, and its value in this direction has been referred to many times in our columns

VERMIN IN THE TRENCHES

To the Editor of THE LANCET

SIR,—In 1902 or 1903 I read in *Blackwood's Magazine* extracts from the diary of a planter who was wandering alone for several days during the Indian Mutiny He became infested with pediculi, and after some days of discomfort hit on the idea of shredding a cheroot and steeping it in water The application of this "tobacco-water" to his body rid him of a nuisance This might be worth a trial and could, I think, be easily done in the trenches An ounce of shag soaked in a quart of water for some hours ought to make a fairly strong *infusion One would not expect* it to kill the ova, however

Norman Walker in his Introduction to Dermatology" writes about pediculi corporis "Jamieson says that a small bag of sulphur worn round the neck next the skin acts as a practical '*charm*'"

I am, Sir, yours faithfully,

Feb 6th, 1915 M R C S & L R C P

ATTACHMENTS TO TELEPHONES

THE following notice in the "London Telephone *Directory*" may serve as a warning to future in*ventors* and so pre*vent* fruitless efforts of ingenuity — Attention is drawn to the fact that subscribers are being induced to purchase appliances for attachment to telephones on the ground that they improve the service *or have some* hygienic advantage *As in* nearly all cases these attachments have the effect of either damaging the apparatus *or* impairing its efficiency—in many cases both —subscribers are reminded that under the conditions of their telephone service the use of such appliances or attachments is in general, prohibited The sale to the public of certain appliances which have no such prejudicial effect has been sanctioned by the Post Office and subscribers should before purchasing any telephone attachments satisfy themselves that their use has received official sanction It is the duty of the Post Office engineers to remove any attachments which have not been officially approved"

FEES UNDER THE MENTAL DEFICIENCY ACT

"DEFICIT" writes "I shall be obliged if any of your readers can give me an idea *as to the fees one should* ask as medical officer under the Mental Deficiency *Act*"

COMMUNICATIONS not noticed in *our present issue* will receive attention in our next

Medical Diary for the ensuing Week.

ABSTRACT OF

An Address

ON

IMMUNITY AGAINST INFECTIOUS DISEASE,

WITH SPECIAL REFERENCE TO

ANTITYPHOID INOCULATION

Delivered before the Statistical and Social Inquiry Society of Ireland on Jan. 22nd, 1915.

By E. J. McWEENEY, M.A., M.D. (N.U.I.),
D.P.H., F.R.C.P. Irel.,
PROFESSOR OF PATHOLOGY, UNIVERSITY COLLEGE, DUBLIN.

Nature, Causes, and Kinds of Immunity.

It is a well known fact that second attacks of infectious diseases are, with few exceptions, rare. In withstanding the first attack the patient has acquired immunity against further onslaughts of the same disease germ. Examination of the blood of such a person, moreover, affords evidence of the presence in it of substances that exercise a deleterious influence on the germ—may, indeed, kill it. The presence of these substances in the blood of the convalescent patient is only a particular case of a general law which may be thus stated: *The entrance of foreign albuminous matter (protein) into the system evokes the production of specific antibodies.* We now call the foreign or intrusive protein "antigen." Ehrlich explains the action of the antigen by supposing that its molecules combine with the receptors or nutritive side chains of the body cells. Should the antigen be poisonous or occupy too many of the side chains the cell may be killed. But if it survives it reacts by producing fresh combining links or receptors, which, being discharged into the blood, constitute the antibody.

The side chains or receptors with their supposed capacities for combining, &c., have never been seen and may possibly not exist. They have been imagined and enable us to visualise a certain concept of how immunity is brought about. That concept may not be right—may not correspond to facts in all particulars. But it certainly does so to a very large extent, and, what is very important, the theory has proved itself a genuinely heuristic one in the sense that inferences based upon it have been found justified by the test of actual experiment. Under the influence of this theory immunity has become a vast and highly specialised department of research and has yielded practical results of the highest importance, with one of which we are this evening concerned.

With regard to antibodies there are two points deserving special notice. In the first place they are only produced when the antigen is introduced parenterally—that is, otherwise than by way of the alimentary canal. The second point is that antibodies are specific—that is, will only combine or react with the antigen that produced them. Recovery from one disease will not protect against another. We term the poisons produced by microbes "toxins." They behave as antigens. During a non-fatal attack of an infectious disease, such as typhoid, the bacilli, consisting as they do of foreign protein, are powerfully antigenic; they stimulate the cells of the individual attacked, with the result that a crop of antibodies is produced specifically directed against the intrusive micro-organisms. Thus there are found (1) opsonins, which lead to the ingestion and destruction of the germs by the white blood cells; (2) antitoxins, which combine with and neutralise its poisons; (3) agglutinins, which cause the bacilli to adhere together and doubtless assist in their destruction; and (4) bacteriolytic amboceptors, which focus upon the bacillus the powerful ferments contained in the blood and thus bring about its dissolution. The consequence is that the attack is foiled. The disease germ is suppressed and got rid of. The patient recovers, and for a time retains in his blood enough of the specific anti-substances to render any further attack from the same quarter impossible. Such a patient is said to be immunised or protected, but the duration of protection varies within wide limits.

Immunity may be *natural* or *acquired*. In natural immunity the man or animal is congenitally incapable of becoming infected owing to the absence from his body cells of receptors capable of combining with the germs or their toxins. Acquired immunity may be the result of (1) an accidental, involuntary attack of the disease contracted in the ordinary way, or (2) the deliberate introduction of the antigen, or the corresponding antibodies by the parenteral path; this is artificial immunity.

Artificial immunity may be (1) active, or (2) passive. Passive immunity is obtained by the introduction into the subject of antibodies ready made. The antibodies are contained in the serum of an actively immunised animal, and this "anti-serum," as it is called, is injected. This procedure has proved of remarkable service against diphtheria and tetanus. Active immunity, on the other hand, is brought about by the reactive forces of the individual himself, elicited by the entrance of the specific micro-organism. It may be induced by the introduction of the disease germ (1) in its primitive unaltered condition; or (2) modified in various ways.

1. Artificial introduction of the germ in the living state and of full virulence is, of course, a dangerous procedure, as the attack so induced may prove fatal.

2. The following are the chief modes of modifying the virus of a disease so as to render it suitable for protective inoculation. (*a*) It may be passed through the system of a more or less insusceptible animal. This is what happens in the only kind of protective inoculation hitherto universally practised—that directed against small-pox. (*b*) The virulence of the micro-organism may be diminished by heat or antiseptics. This is called attenuating the virus. (*c*) The virus may be slowly dried outside the body. In this way Pasteur succeeded in attenuating the virulence of the unseen micro-organism of rabies and converting it into a harmless vaccine. (*d*) The disease germs may be killed by heat or antiseptics. Their dead bodies constitute the vaccine. This is the method most usually employed as against typhoid, and is consequently that which chiefly interests us practically. It has also been found to work well as against paratyphoid, cholera, plague, and dysentery. (*e*) The germ itself may be got rid of by filtration and only its products or toxins may be introduced. This plan only works when the toxins are excreted into the culture fluid, as happens in the case of diphtheria and tetanus. When the poisons remain locked up in the body of the micro-organism, as they do in the case of typhoid, this plan is not applicable. The bodies of

---

* The [illegible] the [illegible] "group reactions" is here passed over.

TABLE III —*Results at Ladysmith and Modder River*

—	Number	Morbidity	Mortality
Ladysmith—			
Inoculated	1 705	35 = 2·05%	8 = 0·47%
Not inoculated	10 529	1489 = 14 14%	329 = 3 13%
Modder River—			
Inoculated	2 335	26 = 1 11%	(*)
Not inoculated	10 931	257 = 2 34%	(*)

* These tables are taken from Russell *loc. cit.* the original publication not being available

It will be noted that Wright claims to have diminished the case incidence by more than one half and the mortality in still greater proportion I feel certain that the method did not on this occasion obtain a fair trial The unpleasant fact remains that out of a total strength of about 381,000 there were during that campaign nearly 58,000 cases of typhoid with over 8000 deaths Some observers reported favourably of the method, such as Tooth,[8] Marsden,[9] Boyd,[10] Osborn,[11] and Cayley[12] But others were not able to agree as to its value (Elliot and Washbourn,[13] and Melville[14]), whilst yet others[15] went so far as to assert that the number of cases and deaths was increased by the inoculation The *ad interim* verdict at the time was "not proven" The War Office suspended the practice for the time being, and appointed a Commission to report upon it This Commission, which was presided over by Dr C J Martin, F R S., entrusted the experimental part of the work to Sir W B Leishman

By direction of the Commission inoculations were again taken up amongst the personnel of a number of selected units serving abroad, chiefly in India. The procedure was carried through in the most thoroughgoing and systematic manner Careful attention was paid to the incidence of typhoid upon the units under observation, the most modern methods of diagnosis being employed by medical officers specially trained for the purpose I reproduce the main results as reported by Sir William Leishman to the International Medical Congress held in London in August, 1913[16] The observations were made on 24 selected test units The period covered extended from December, 1904, to June, 1909

TABLE IV —*Results of Antityphoid Inoculation among Troops on Foreign Service (Leishman)*

—	Total strength	Cases	Rate per 1000	Deaths	Rate per 1000	Case mortality
Not inoculated	8 936	272	30 4	46	5 14	16·9%
Inoculated	10,378	56	5 4	5	0 47	8·97%

In another table Leishman sets forth the typhoid incidence and mortality in India for the past 23 years, but it will suffice to confine our attention to the last 11 years, beginning in 1902 and ending in 1912

TABLE V —*Typhoid Fever in India from 1902 to 1912 (Leishman)*

Year	Admissions.	Deaths	Admissions per 1000 of strength	Case mortality per cent
1902.	1012	260	16 7	25 69

*1912	118	26	1 7	19 0

* Since writing the above a statement has appeared to the effect that in 1913 the deaths from typhoid in our Indian army were reduced to 3

Now, the practice of inoculation was re-introduced in the year 1905, but it was not until 1909 that the number of men inoculated was large enough to influence the general statistics "From that year," says Leishman, "there has been a steady and very remarkable decline, the figures for each successive year constituting a fresh low record, until in 1912 we find that there have been only 118 cases in the whole of the British Army in India—a gratifying contrast to the large figures recorded in the past" (In 1897 there were 2050 and in the following year 2375 cases) Leishman then proceeds to disclaim the view that this great diminution is exclusively attributable to the inoculations "Improvements," he says, "in general sanitation, improved methods of diagnosis, the detection and isolation of 'carriers,' have undoubtedly all played a part, but my strong personal conviction, shared, I am glad to know, by many of my brother officers, is that the reduction is in the main due to the extended employment of anti typhoid vaccine"

History of the Method in America

The remarkable results that have been achieved in the American army by the use of the method are mainly due to the energy and perseverance of Major F F Russell, M.D, Professor of Bacteriology in the United States Army Medical School, Washington, who has recorded his experiences in a valuable paper[1] The fearful havoc wrought by typhoid among the American troops during the war with Spain called imperatively for active measures, and in 1908 Major Russell was directed by his chief, Surgeon General O Reilly, to proceed to Europe and familiarise himself with the technique of the preparation of the vaccine Russell accordingly betook himself to London, where he worked under Leishman and his assistants and brought home the necessary experience and the special strain of typhoid (Rawlings) used in the preparation of the British army vaccine The following year Russell began by inoculating his own laboratory staff The news spread, and practically all the medical officers in and about Washington volunteered and sent their wives, children, friends, and servants Then the corps of hospital attendants came in, and by the end of 1909 there had been vaccinated the bacilli may, however, be allowed to dissolve (undergo autolysis) or they may be pulverised at the temperature of liquid air, or they may be forced by enormous pressure to yield up their toxins, which may then be used for inoculation

INCIDENCE OF TYPHOID ON THE GENERAL POPULATION

Before considering the need for a new method of combating a disease, it is proper to ask ourselves how the disease has been influenced by the ordinary sanitary measures prescribed by the State or adopted by up to date units of sanitary administration When we come to do this in the case of typhoid we find that there has been of late years a remarkable reduction in the incidence of that disease

In Great Britain 20 years ago the death rate per million from this cause was over 300, in 1912 it had fallen to 44—the lowest recorded In Ireland there was also a fall though not so pronounced In 1903 the deaths numbered 480 and in 1913 289, the average for the past 10 years being 371. The rate per million dropped from 109 in 1903 to 53 in 1912, the average for the 10 years being 84 In many of our great cities the same thing has occurred Thus in Liverpool in 1894 there were 1350 cases with 248 deaths, whilst in 1913 there were only 153 cases with 33 deaths In Glasgow the case rate per 100,000 was 138 6 in 1891 and the death rate 21 8 In 1913 the former had sunk to 23 2 and the latter to 0 36 In other cities the fall is not so great In Manchester, for example, there were in 1899 381 cases with 73 deaths, and in 1913 292 cases with 47 deaths, the death rate per 100,000 falling during the 15 years from 13 to 6 In our own City of Dublin the cases 20 years ago numbered 813 and the deaths 104 Last year the cases had fallen to 287 and the deaths to 33 This latter figure corresponds to a death rate of 11 per 100,000, the average for the previous 10 years being 16

These figures afford convincing proof of the fact that under ordinary civil conditions of life, general sanitary measures, such as pure water, good methods of sewage disposal, attention to the food supply (supervision of shell fish, of milk), and certain specialised measures such as the discovery and isolation or cure of carrier cases, have proved effective in diminishing the prevalence of typhoid

INCIDENCE OF TYPHOID ON TROOPS IN THE FIELD

Experience has shown that when men are huddled together in camps or trenches or in beleaguered towns under war conditions, typhoid tends inevitably to break out amongst them and speedily becomes a regular pestilence

Table I. sets forth the figures for typhoid in some recent campaigns

TABLE I[1]—*Losses caused by Typhoid in some Modern Wars*

War	Strength	Typhoid cases	Typhoid deaths	Killed in action died of wounds	Died of disease
Franco-German, 1870-71 German army	—	73 393	6 965	28 209	15,2 0
Spanish American 1898, American army	107 973	20 738	1 580	2 3	2,565
Boer War 1899-02 British army	380 605	57 684	8 022	7 702	13,250
Russo-Japanese, 1904-05 Russian army	—	17 033	—	34 000	9 300

From this we see that during our war with the Boers we suffered greater losses from typhoid bacilli than from the bullets of the enemy The reason for the terrible ravages of this disease during war time is the greater difficulty there is in disposing of the germ laden excretions of the human body under the conditions then prevailing Typhoid in military encampments is not, as a rule, water borne The specific germs are introduced by mild, undiagnosed cases, and by germ carriers The latrines and trenches thus become infected and the bacilli are widely spread through the agency of "the three F s—Food, Flies, and Fingers"—so that all are brought in contact with the germs of the disease, and all that are susceptible take it

HISTORY OF PROTECTIVE INOCULATION—AND ITS RESULTS

For such exceptional conditions as those just referred to exceptional measures are obviously called for It is to the labours of our gifted fellow countryman Sir Almroth Wright that we are indebted for the introduction of a method that has now proved itself to be an effective weapon against the spread of typhoid In his praiseworthy endeavours Wright has been most ably seconded by Colonel Sir W B Leishman, R A M C, whose untiring industry has placed the procedure on a sound basis of experiment and observation, and thus powerfully contributed to its now well nigh universal adoption in the armies of all the leading countries

Wright's first steps in this matter were taken so far back as 1896, and are recorded in a paper[2] which was concerned with a totally different subject. In this paper he speaks of two men and an animal (horse) as having received inoculations of dead typhoid bacilli Early in the following year[3] he describes the changes in the blood of 17 persons similarly inoculated. Meanwhile it is only fair to state the subject was being energetically worked at in Germany by Pfeiffer and Kolle, who published[4] an account of their systematically conducted experiments a few months before Wright's first paper appeared Wright's work was, however, quite independent of theirs, and the development of the method in this country under Wright and Leishman was quite original and not in any way due to German influence

In 1898 Wright inoculated 4000 men of the Indian army[5] Shortly afterwards came the first application of the new method in civil life, at the Barming Asylum, where there was a serious outbreak of typhoid, and 100 of the attendants were inoculated not one of whom contracted the disease[6]

As early as 1900 the method still in its infancy, was tried here in Dublin at the Richmond Asylum, which was at that time suffering from a severe visitation of typhoid. At the instance of the late Dr Conolly Norman, Professor Wright was invited to make a trial of his method, and the work of carrying out the inoculations was intrusted to the assistant medical officer, the late Dr Henry M. Cullinan

Among the uninoculated, 114 in number (all nurses), there were 17 cases with 4 deaths Among the inoculated 500 in number (all patients), there were 7 cases with one death Of the 7 cases, 3 were already infected at the time of inoculation, and must be left out of account The case incidence per cent was therefore 14 9 among the uninoculated, as compared with 0 8 among the inoculated and the death rate 3 5 as compared with 0 2 Only one inoculation was given and the reactions were severe, necessitating the patients staying in bed for three or four days

The Boer War of 1899-02 afforded the first opportunity of testing the new method on a really large scale Its use was sanctioned by the War Office but was left optional with the individual Some 400 000

During the period in question there was no change of importance in the general sanitary administration, and nothing to account for the disappearance of typhoid save the introduction of prophylaxis by inoculation This result must surely claim attention as a remarkable example of the annihilation of disease by the weapons which bacteriological research has placed in our hands

Table IX.—*Monthly Incidence of Typhoid amongst United States Officers and Men* (*Russell*)

Year	January	February	March	April	May	June	July	August	September	October	November	December	Total for 9 months
Voluntary—													
1908	5	6	4	2	3	11	14	31	25	26	12	8	101
1909 ..	4	10	6	4	11	15	26	14	16	45	20	6	106
1910 ..	8	11	1	4	2	6	12	27	21	16	20	11	92
1911	3	3	3	7	4	4	4	7	4	4	1	0	39
Compulsory—

*1913 ..	0	0	0	0	0	0	0	0	0	—	—	—	0

* Only one case occurred during the last quarter of 1913

Professor McWeeney then gave brief summaries of the successful results accomplished by means of antityphoid inoculation in other countries, and concluded his address with an account of the reaction caused by inoculation and a statement of the various classes of the population which should be inoculated

[During the discussion on the above paper figures taken from the Report of the Army Sanitary Committee on the Prevalence of Typhoid in the British Expeditionary Force during the present war were given by one of the speakers to the following effect The total cases numbered 212 of whom 22 died Of the 212 cases, *173, or 81 5 per cent, and all the deaths occurred amongst the uninoculated* Of the 39 inoculated cases 28 occurred amongst those who had received only one dose or who had been inoculated more than two years ago, whilst only 11 occurred amongst those regarded as fully protected These results, convincing as they are, would be still more so did we but know the actual numbers of the two classes, inoculated and uninoculated It would then be seen that the vast majority of the cases (81 5 per cent) occurred amongst the comparatively few uninoculated men]

Royal Institution —At a general meeting held on Feb 1st the Duke of Northumberland, K G, President in the chair the special thanks of the members were returned to Dr H D Rolleston for his generous gift in the name of Miss Davy (niece of Sir Humphry Davy) of a bust of Sir Humphry Davy The bust as reported in our last issue was presented to the institution on behalf of Dr Rolleston by Sir James Dewar on Jan 22nd

---

EMBALMMENT OF SEPTIC WOUNDS

IN CASES OF GRAVE DISORGANISATION OF LIMBS CAUSED BY RIFLE OR SHRAPNEL BULLETS OR SHELL FRAGMENTS

By Dr. LOUIS MENCIÈRE

OF RHEIMS MÉDECIN-CHEF TO THE HOSPITAL OF THE COMPASSION AT COMPIÈGNE CONSULTING SURGEON FOR THE CENTRE.

(*Translated for* The Lancet)

Five months of war spent as an operating surgeon in our hospitals at the front and at the base and 20 years of surgery, for the most part that of the bones and joints, embolden me to offer my opinion as to the best way of setting about the treatment of extensive damage to the limbs I therefore bring forward this note on a proceeding and a formula which imply a radical change in the course of gunshot wounds, of which it is desirable that our comrades of the British army should be able to avail themselves

If it were possible on the battlefield (which it is not) the preservation of a limb would depend entirely upon the primary cleansing of the wound and on the first dressing I shall not easily forget how a good friend of mine, a *directeur d'ecole* at Rheims, while out shooting received the contents of both barrels of a fowling piece in his foot at point-blank range The bones were smashed, the torn foot was attached to the leg only by a strip of skin, &c, on its inner side, but the chief nerves and vessels escaped The wound was swabbed out immediately with some alcohol, such as is used for spirit lamps, and which I found in a farmhouse That evening the patient was taken to my hospital. A careful wound toilet was performed, all fragments of boot, gun wads, &c, being removed, and the tendons and some of the soft parts were sutured The foot was preserved in good shape and with good movement This result was entirely owing to the immediate treatment of a part which was literally smashed, and to the subsequent complete and thorough attention which could be given in specially favourable conditions

Are such conditions possible on the battlefield? No, absolutely No! Want of space, of skilled help, of facilities of all sorts, and the necessity of rapid evacuation are such that our wounded arrive at the ambulance or the field hospital in conditions very different from those of the case which I have mentioned Let us consider the state of things existing at the front, for there is one surgery of the front and another of the base, and when the time comes for discussion of these matters I would advise those who have been operating near the fighting line to discuss things among themselves, and those who have been operating in the rear only to speak of what they have seen Everyone would be the gainer

We are considering then the surgery of the front First of all, there is the question of seasons Wounds in winter are not quite the same as those in summer, for the germ of sepsis is capricious and needs favourable climatic conditions for its development When the ground is cold its virulence is diminished Thus, in the hospital in which I operate gas gangrene, which was truly appalling in its frequency and the rapidity of its course in the beginning of the campaign, has almost disappeared in this winter season But when gas gangrene appears I say without hesitation, however slight it seems, if only you feel that your antiseptics, 1887 persons The following year 16,073 people were done During 1911 the influx of volunteers still continued, and the authorities, fortified by the experience of 20,000 vaccinations without a mishap, felt justified in making it compulsory upon all that were to participate in the manœuvres on the Mexican frontier The order was issued in March, 1911 The results achieved fully justified the step taken Major Russell refers to the three divisional camps near the border, each camp being in full occupation for four months At the Galveston (Texas) Camp there were 4500 men, at San Diego (California) 3000, and at San Antonio 13,000 At Galveston, though there were 102 cases of typhoid amongst the civil population (with whom the soldiers mixed freely), *there were no cases amongst the troops* From San Diego only two cases were reported, one of which was doubtful Major Russell draws an interesting comparison between the experience at the San Antonio camp in 1911 and that at Jacksonville (Florida) in 1898 These two camps, each of approximately equal size, were maintained for the same length of time They were situated in the same latitude, and each had artesian well water of excellent quality Yet in 1898 there were over 2500 cases of typhoid at Jacksonville, with 248 deaths, on a strength of 10,759 men, while at San Antonio in 1911, on a strength of 12,801 men, there were only two cases with no fatality

Nor was the possibility of infection lacking, for during the duration of the camp there were 47 cases of typhoid with 19 deaths reported among the civil population, with whom the military freely mixed Every allowance being made for improved sanitary measures and the fact that the 1898 camp was in war time, whilst peace prevailed in 1911, the result must be looked upon as the signal evidence of the power of inoculation to save encamped troops from this disease

The next step in the American campaign against typhoid was the extension of the vaccination order to all recruits This was done on June 7th, 1911 Vaccination against small pox is carried out at the same time

"If the vaccinia be severe," says Major Russell, "the second dose of typhoid prophylactic is postponed a few days, but in no other way has it been found necessary to deviate from this routine of simultaneous vaccination against the two diseases The two vaccinations are completed by the time the man has been 20 days in the service Revaccination against both diseases is carried out, according to the present regulations at the beginning of each four year period of enlistment This is not because the immunity has by that time disappeared for its duration is not yet known It, no doubt, diminishes gradually, as is the case with that from small pox, yet in the service it is desirable to maintain the army in a maximum state of protection against infection at all times, and it does not seem advisable to omit vaccination until an outbreak of typhoid shows the disappearance of all immunity Small pox has been almost entirely suppressed, there were only five cases among the American troops in 1911 with no fatalities and typhoid has ceased to be the scourge of former times"

I have thought it well to quote this passage from Major Russell's paper in view of its applicability to the situation created in our armies by the present war I am clearly of opinion that only by making the inoculation compulsory shall we be able to get the best results from it, and I venture to express the hope that our military authorities, uninfluenced by the protests of 'faddists, may before long see their way to follow in the footsteps of the Americans

On Sept 30th, 1911, compulsory prophylaxis was extended to all persons in the American army under 45 The results are set forth in the tables which I reproduce —

TABLE VI —*Typhoid Fever (United States) among Enlisted American Troops (Russell)*

Year	Mean strength	Cases	Deaths	Cases per 1000	Deaths per 1000
1901 ..	26,515	250	17	9·43	0·64
1902	39 736	341	34	8 58	0·85
1903 ..	42,264	246	12	5 82	0·28
1904	43 940	247	12	5 62	0·27
1905	42 834	153	13	3 57	0 30
1906	40 621	230	12	5·66	0·29
1907 ...	35 132	124	7	3 53	0·19
1908	46 316	136	11	2·94	0·23
1909	57 124	173	16	3·03	0·28
1910	55 680	129	9	2 32	0·15
1911	55 240	44	6	0·80	0 11
1912	58 119	15	2	0 26	0·03

TABLE VII —*Showing the Number and Proportion of Typhoid Fever Cases contracted before Enlistment and among the Protected Officers and Enlisted Men (United States proper only) (Russell)*

Year	Total Cases	Total deaths	Infected prior to enlistment	Among the vaccinated	
				Cases	Deaths
1909	173	16	(?)	1	—
1910	129	9	(?)	[illegible]	—
1911 ..	44	6	(?)	7	—
1912	18	3	5	6	—

TABLE VIII —*Typhoid Fever, 1901 to 1912, for the Whole Army, Officers and Men, at Home and Abroad (Russell)*

Year	Mean strength	Cases		Deaths		Occurring among the vaccinated	
		Number	Ratio per 1000	Number	Rate per 1000	Cases	Deaths
1901	81 835	552	6 74	74	0 98	—	—
1902	80 778	565	6 74	69	0 85	—	—
1903	67 643	343	5 14	30	0·44	—	—
1904	67 311	293	4 35	23	0·33	—	—
1905	65 663	206	3 14	20	0·30	—	—
1906	65 159	373	5 72	18	0 27	—	—
1907	62,523	237	3 79	19	0 30	—	—
1908	74 692	239	3·20	2	0 31	—	—
1909	84 077	282	3 35	22	0·26	1	0
1910	81,434	193	2 3	14	0·17	7	0
1911	82,802	70	0 85	8	0·10	11	1
1912	88,478	27	0·31	4	0 04	2	0

From Table VI it will be gathered that the case rate per 1000, which was 3 03 in 1909 and 2 32 in 1910, fell in 1911, coincidently with the widespread adoption of vaccination in that year to 0·80 and in 1912, the first year it was *compulsory* to 0 26 Remarkable as are these results they are surpassed by those of 1913 for the first nine months of which figures were available The following table shows the monthly case incidence for the past six years

Rheims, this is what five months of war have taught me and what it is my duty to impart to others The following is the treatment recommended Successive washings of the wound with the three antiseptics after atypical operations when, as often, necessary Embalmment of the wound (permanent dressing) with gauze wicks soaked in the solution, the formula of which will be found below For three or four days wash again with the three antiseptics, after which, remembering the susceptibility of the cells, only wash with hydrogen peroxide 1 in 3 or 1 in 4, and again embalm Repeat the dressing daily It is a mistake to advise that the dressings should not be removed A wound which is closing up necessitates an intense phagocytosis, an irruption of white cells which clog the wound and which form a liquid which it is always best to evacuate in order to avoid resorption It is for this reason, too, that you must not close the wounds, but drain them freely with glass drains if, more lucky than I, you can get them. Embalmment of wounds thus, following the formula given further on, is a powerful antiseptic deadly to microbes but sparing the cells, calling forth the phagocytes and constituting a stimulant to the wound It is the means which has succeeded best with me after having tried nearly everything—formol, salicylic acid, tincture of iodine, and iodine vapour itself I do not decry tincture of iodine employed for a first dressing, but this method can not be repeated, for if it kills the microbes it also causes necrosis of cells and leaves a surface which is an excellent culture medium, but not a good defence This is my formula (A) —

Iodoform	10 grammes
Guaiacol	10 ,,
Eucalyptol	10 ,,
Balsam of Peru	30 ,,
Ether	100 ,,

—used to soak the wicks of gauze or to be injected into the sinuses with a Roux's syringe If you lack hydrogen peroxide, or if you are simply prodigal, you will do well with solution B for washing the wound before embalmment, which differs from A only in the quantity of ether, which is 1000 instead of the 100 of solution A In case of idiosyncrasy or intolerance after a few days' treatment (which is exceptional) omit the iodoform from the formula This is the "secret formula" with which my fellow workers have good naturedly twitted me, knowing well, however, that I impart it freely to everyone who will do me the honour to employ it This is the embalmment formula, not of the Pharaohs, but simply that of your Rheims colleague

---

DONATIONS AND BEQUESTS —By the will of the late Mrs Mary Ann Haines Timmins, of Moseley, near Birmingham the testatrix left £1000 to the Birmingham University and a similar amount to the Birmingham District Nursing Society £100 to her medical attendant and £100 each to the Relief Fund of the Birmingham General Dispensary the Children's Hospital Birmingham the Birmingham and Midland Ear and Throat Hospital, the General Hospital Birmingham the Queen's Hospital Birmingham and the Birmingham and Midland Eye Hospital —By the will of the late Mr William Prenton, of Liverpool the Stanley Hospital, the Royal Infirmary the Cancer and Skin Hospital, the Eye and Ear Hospital the Northern Hospital, and the Southern Hospital of that city will receive £500 each —St Bartholomew's Hospital will benefit by £4500 and a quantity of Metropolitan Consolidated Stock under the will of the late Mr Ernest Baker From the Merchant Taylors Company the same hospital has received £500 being the second half of a grant made in 1913

THE PREVENTION OF FROST-BITES

BY SHERIDAN DELÉPINE, M B, C M EDIN, M.SC,
PROFESSOR OF PUBLIC HEALTH AND BACTERIOLOGY UNIVERSITY OF MANCHESTER, ETC.

FROM the accounts in the papers, both medical and lay, it is clear that our soldiers have suffered much from the effects of wet and cold since the beginning of the winter in Belgium and Northern France It has probably occurred to many people that if these men could have been provided with waterproof coverings for their feet and legs they would have been saved from much suffering and from various sources of incapacity It seemed, however, hopeless to suggest that they should be supplied with fishing boots or stockings, the cost of which is quite prohibitive For some time I have been engaged trying to ascertain whether there was in the market any waterproof material thin enough to be worn between stocking and boot and cheap enough to meet the financial requirements of the case Fabrics rendered waterproof with indiarubber seemed too costly, and I came to the conclusion that oxidised linseed oil was the most promising waterproofing agent for the purpose in view Oiled silk appeared to have the properties needed except elasticity, but experience showed me that a straight bag of silk, rendered waterproof with heated linseed oil mixed with a suitable proportion of a drier, was so thin and pliable that it could be easily drawn over a *thick* stocking, and protected against wear and tear by a second stocking drawn over it after it had been adapted to the shape of the foot and leg by simply twisting it Owing to the thinness, softness, and pliability of the material the foot covered with it can be introduced into the boot without difficulty, and it is possible to walk for several hours with the feet protected in this way without the oil silk bag being felt at all At first I experienced some delays in obtaining a completely waterproof oil silk bag of suitable shape owing to the difficulty of making strong and waterproof seams I had just obtained satisfactory results at a very small cost (less than 2s for two leg bags) when I read in this day's issue of the *Times* (Jan 26th, p 7) an article on "Wader Stockings," which revealed to me the fact that Mr F B Behr had had the same idea, and that a serviceable article, in all probability, more elegant and better made than my bag, was already available and had actually been adopted by the army

As the object which I had in view had thus been fulfilled there would have been no purpose in my writing about this matter had I not carried out some experiments which indicated to what an extent thin waterproof bags can protect the feet and legs against the effects of immersion in ice cold water These experiments were conducted as follows The bulbs of two bomb recording thermometers were fixed to the skin of the foot and ankle immediately behind and below the external malleolus The bulb was firmly placed against the skin and covered externally with a layer of indiarubber plaster to prevent the free access of air or water About one third of the surface of each bulb was in close contact with the skin To maintain contact the ankle was bandaged One foot was then covered with two thin woollen socks, the other foot, after being covered in the same way, was inserted into one of my oil silk bags To permit free and *equal* access of including hydrogen peroxide, are becoming ineffective, amputate—amputate without hesitation, it is the sole remedy that will save the patient's life Select the site of amputation, do not mutilate too much, for even in tissues already indurated (*marbre*), after readjustment of the stump if needed, you will succeed Embalm the stump, as will be described later, not with the view of preventing gangrene, but to prevent ordinary septicæmia, which lies in wait for the stump and would lead to its dissolution In other cases, in which it is not a question of gas gangrene but of an ill defined, subacute septicæmia, if after embalming the general condition remains bad, if the complexion is earthy, the pulse small and rapid, the respiration—above all, the respiration—rapid and difficult, the temperature raised, if, in one word, the patient is threatened with death from septicæmia, amputate again

Note that I give this advice, although by profession I am in the habit of preaching conservatism *à outrance* in the ordinary circumstances of surgery, even when severely crushed limbs are in question With these reservations it does not follow that conservative surgery must be—as it is with our adversaries—considered a Utopia Nor does it follow, as we seem to have thought at first, that it is an easy thing and simple and regular in practice

For 20 years I have seen wounds of the limbs of all kinds and from all causes, but never have I seen wounds take the course that they do in the run down patients living under the present conditions I consider that a few aseptic or antiseptic washings and dressings will not suffice, although they may be enough in other circumstances to preserve the limb At the outset one thing is gained the knowledge that it is absolutely necessary that asepsis shall give place to antisepsis—to antisepsis *à outrance* Let us do homage to the immortal Lister and to our great Championnière! I yet remember what the latter told me at the Congress in London in 1913 "In 1870 I took a great deal of trouble to get a barrel of carbolic acid placed in an ambulance wagon I saw the barrel again after the campaign Its contents were intact!" Fortunately, it is no more thus, and we know that surgeons used to abdominal operations are now abandoning the prejudices born of the necessities of their usual work—for the peritoneum is not tolerant of antiseptics—to return to antiseptics when it is a question of the surgery of the limbs Bone, joint, and muscle, and even tendon surgery is not possible without antiseptics—how many tendon-transfers, arthrotomies, or resections have been done in vain because the surgeon has been satisfied with cleanliness instead of antisepsis I spent a month in a hospital in the rear, where, for reasons not necessary to state, antisepsis was nearly impossible—a hospital in course of formation operators not very enthusiastic, difficulties of supply, asepsis almost exclusively employed in operations and dressings, at most a few washings with permanganate The results were deplorable, heartrending, upsetting all my recollections and all that I knew and had seen of the surgery of the limbs

When I was called to the head of a surgical centre in a unit where I could dispose of powerful antiseptics I found once more the conservative surgery to which I was accustomed Except for the cases of gas gangrene and acute septicæmia I was able as in time of peace to preserve a smashed limb, an elbow, a humerus broken up in the midst of an intricate and septic wound, or a fracture of the thigh complicated by comminution and septic wounds In a word, without trying to be conservative always, I am able to preserve the limb often or almost always That, as it seems to me is in the circumstances something appreciable, which everyone can obtain if he likes, if he will believe it

Antisepsis, then, dominates all this war surgery I do not believe that it can be applied on the battlefield Later, when the subject is discussed I shall demand many motor cars, abundant means of transport, not to move the wounded far into the interior, where necessarily they would arrive in a miserable condition, but to take them 20 or 25 miles from the firing line, where in well established units one could make as good a job of it as we do here

The wounded man arrives, let us say, with a septic, intricate wound, with the bone splintered The treatment must be economical of tissues, atypical operation, removal of loose splinters and of sharp edges likely to wound vessels, cleansing of the wound, above all multiple incisions well placed, drainage of the wound, successive lavage with the three antiseptics—sublimate 1 in 1000, carbolic acid 1 in 40, and peroxide of hydrogen 1 in 3 Why these three antiseptics? Because all germs, spores, and microbes, whether anaerobic or aerobic, are not equally sensitive to the three For the wound holds all sorts of undesirables, and one must give it what it wants for each *Each of the three* antiseptics is particularly adapted to a peculiar microbial variety Successive lavage of the wound with the three antiseptics, such is the first antiseptic dressing, which acts not only antiseptically, but in a mechanical manner in drawing out pus and all sorts of débris

There remains the permanent dressing, in our practice it holds a place apart, because I do not hesitate to state that it changes the aspect and the course of wounds, and that it is the best aid to conservative surgery that I have been able to find after trying everything Iodoform, dear to the old fashioned, associated with guaiacol, eucalyptus and balsam of Peru, forms an application which changes the course of healing of the wounds, often of the most septic, and gives unlooked for results Hospital gangrene, atonic sanious wounds disappear to give place to a wound which is bright carmine red, with fleshy, well nourished granulations, a wound no longer septic, but accompanied by healing which has sometimes seemed to me extremely rapid Such was the case of a rifleman, who had a hideous infected wound of the calf with all the muscles hanging as if detached by a rake I showed this patient at an inspection in the state described and I showed him again three weeks later with a calf of normal form and almost completely cicatrised A Zouave, whose forearm was saved, when amputation had seemed at first the only possible course is an instance in point, another Zouave who was brought in with a deep intricate shrapnel wound of the shoulder, the bone smashed and draining badly, occurs to my mind, his wound changing appearance fast and becoming covered with healthy red granulations a patient whom I could evacuate quickly These wounds, had they been in my other unit, where antisepsis was practised badly or not at all would not have healed and after operation would have remained unhealed

This is what is beyond my personal experience acquired at my clinique of orthopædic surgery a that there would be a deep cavity, one less likely to heal than its predecessor, and with the sphincter ani destroyed, an undesirable condition of things for the patient It was decided, therefore, to try radium Dr E Napier Burnett, who had had experience of the use of radium, saw the patient with me, and although the growth was involving both passages, and presented therefore not an encouraging condition of things, we thought there was just the chance that radium might do good Accordingly, we obtained from the Radium Institute, London, a tube of radium emanations Covering it with gauze, the tube was gently inserted into the vagina and left there for 24 hours On removing the tube the mucous membrane of the vagina was seen to be reddened, and on the following day it was slightly inflamed A mild muco purulent discharge followed, but there was never any hæmorrhage beyond a few drops on the dressing on two or three occasions Within eight days the inflammation had subsided There was never any unpleasant odour attendant upon the discharge nor did sloughing occur By the end of six weeks the growth had become distinctly smaller and more clearly defined A breach in the mucous membrane which had occurred in the active stage of the inflammation, and from which pus had for a period exuded, gradually closed, the hard mass continued to shrink, and four months after the application of the radium it had entirely disappeared, leaving a healthy vaginal mucous membrane, tissues underneath soft and healthy to the feel, and apparently a normal septum between vagina and rectum No trace of the growth now remains The patient has put on several pounds in weight, looks many years younger, and the bladder and rectal functions are normal She is leading an active and vigorous life and is looking the picture of health

The application of radium in this apparently hopeless case of recurrent cancer of the vulva more than exceeded the expectations of Dr Burnett and myself

Newcastle-on Tyne

NOTE ON A SUCCESSFUL METHOD FOR THE EXTERMINATION OF VERMIN INFESTING TROOPS

By S MONCKTON COPEMAN M D CANTAB,
F R C P LOND, F R S,
LIEUTENANT-COLONEL, R.A.M.C. (T) DIVISIONAL SANITARY OFFICER
FIRST LONDON DIVISION (T.F)

WITHIN about a couple of months of the troops of the 1st London Division coming into camp under canvas at Crowborough I learned through the medical officers in charge of some of the battalions that a certain number of the men under their charge were experiencing the unpleasant effects incidental to infestation by lice Steps were at once taken to deal with the matter, but our efforts were at first somewhat handicapped owing to the fact that not only at that time had the men not been supplied with a second service suit, but that a number of those affected were found not to be in possession of a second shirt or change of underclothing Moreover, it was not possible to obtain assistance from the rural sanitary authority of the area in the work of disinfection, owing to their not possessing any apparatus for the purpose of dealing with infected clothing and blankets

As a matter of first instance all the battalion medical officers were called together for the purpose of informing them as to the various aspects of the question, including the life history of the body louse, *Pediculus vestimenti*, an excellent description of which, by Professor A E Shipley, was published in the *British Medical Journal* for Sept 19th, 1914 At the same time commanding officers were communicated with as to the necessity for ensuring that all the men under their command should be provided with at least a second shirt, and if possible a complete change of underclothing Further difficulty was experienced in providing baths for the men, there being no means at hand of obtaining hot water in large quantities This was eventually obviated by the purchase of several large second hand galvanised iron tanks, which were set up near the ablution place in each camp These tanks were supported over a central trench on bricks laid in puddled clay One end of the trench, which extended beyond the tank at either extremity, was fitted with a chimney built up of old bricks, drain pipes, and puddled clay, while the other end was used as a stokehole On lighting a fire in the trench it was found that even where no cover was provided for the tank the contained water, to the amount of 200 gallons or more, could usually be brought to the boiling point in about an hour Bathing was carried out in an adjoining marquee, or in some instances in an empty house Hot water from the tanks was carried in buckets and poured into galvanised iron wash tubs in which the men could stand. Recently, however, the troops have been moved into huts, where ablution rooms and bath rooms supplied with hot and cold water are provided

The further details of treatment are briefly indicated in the following copy of a memorandum which was distributed to all the medical officers of the Division —

To the Medical Officer

TREATMENT FOR DESTRUCTION OF VERMIN

Arrangements should be made for the bathing of affected individuals and other inmates of infected tents After drying themselves, men to lather their bodies with cresol-soap solution,[1] especially over hairy parts, and to *allow the lather to dry on*

Shirts to be washed in cresol soap solution made with boiling water

Tunics and trousers to be turned inside out and rubbed with same lather, especially along the seams *Lather to be allowed to dry on the garment*

The materials can be obtained from the A.S C on indent authorised by A.D M S in the form attached

(*Form attached*)

To the Commanding Officer,
Army Service Corps,
1st London Division, T F

The following articles are required for the purpose of treatment for vermin Please supply

Jeyes Fluid
Soft Soap

Signed
Medical Officer

Address
Date

Infected blankets were at first treated by soaking them in cresol soap solution, after which they were sent to a neighbouring laundry to be washed, a cold water to the stockings covering the two feet, boots were not put on, but, as I have previously explained, they could have been worn comfortably After an interval the temperature of the skin under those conditions was recorded The two feet were then plunged into 9 to 10 inches of cold water without disturbance of the recording apparatus Ice was then gradually added to the water until the temperature was reduced to + 6° C in one experiment and − 1° in another experiment Some salt was also added in this case In a third experiment only the protected foot was placed in the water to which ice and salt had been added until the temperature had been reduced to from − 2° C to − 4° The results obtained may be summarised as follows —

---

[1] Water ... 10 gallons
Jeyes fluid ... 1½ ounces
Soft soap ... 1½ pounds

Experiment 1, with Oiled Bag (some water penetrated through a pinhole)

Stages	Intervals of time	Indicated temperature in °C at the end of each interval. Foot protected	Foot unprotected	Water	Air
A. Thermometer fixed to skin	20 min	23°	24°	—	12°
B Oiled bag placed over one foot	20	26°+	26°	—	
C Both feet placed in water	7	26°	26°	20°	,
D Plain ice added to the water	45	24°	12°	6°	,

Total duration of experiment 92 minutes

Experiment 2, with Cloth Bag water proofed with Indiarubber (some water accidentally penetrated into the bag)

Stages	Intervals of time	Foot protected	Foot unprotected	Water	Air
A. Thermometer fixed to the skin exactly as in the previous experiment Feet warm	30 min.	26°	26°	—	11°
B Mackintosh bag placed over one foot	7 ,,	26°+	26°	—	
C Both feet placed in water	15 ,	26°+	22°	20°	,
D Ice and salt added to water	30	20°	7°	° to −1°	,

Total duration of experiment, 82 minutes

Experiment 3, with Foot Placed in Oiled silk Bag

Stages	Intervals of time	Foot protected	Foot unprotected	Water	Air
Foot feeling cold before being placed in bag	15 min	24°	—	—	12°
Foot placed in water	5	24½°	—	10°	
Ice and salt added to water Foot motionless	5	24°	—	4°	11°
Foot moving within bag ..	7	24½°	—	3°	
More ice and salt added	7 ,	24°	—	−2°	
,	30	23° to 24½°	—	−2° to −4°	

Total duration of experiment 69 minutes

Experiment 1 —When the feet were removed from the iced water the protected foot felt a little colder than normal but quite comfortable The unprotected foot felt numb The skin was very pale and felt very cold to the touch movements were difficult

Experiment 2 —On removal from the iced water the protected foot felt cold but quite comfortable The unprotected foot felt very numb movements of toes were very difficult and accompanied by cramps

Experiment [illegible] —When the foot was removed it felt quite comfortable

During the experiments the protected foot felt slightly cold when motionless, but not uncomfortable Movements of toes were generally followed by a slight rise of the skin temperature

From these short, incomplete, and imperfect experiments which I conducted upon myself it is clear that the wader stocking or the waterproof bags, such as I have described, may reasonably be expected to have a protecting influence and that their use will in all probability be attended with a diminution in the frequency of frost bites The same waterproof material may if thought desirable be also used for protecting other parts of the body

Manchester January [illegible]

RADIUM AND ITS EFFICACY IN CANCER OF THE VULVA

By Sir THOMAS OLIVER M D Glasg , F R.C P Lond ,
PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE
UNIVERSITY OF DURHAM COLLEGE OF MEDICINE,
NEWCASTLE UPON TYNE.

Radium is still on its trial For this reason any case in which it has been tried and has been of signal service ought to be published It is in inoperable cases of malignant disease where removal of the growth by the knife is impossible or if attempted is likely to leave the patient worse than before the operation, that the application of radium is worthy of the attention of members of the medical profession

A widow, aged 62, mother of a grown up family, consulted me nearly a year ago on account of a hard nodule in the lower part of the left side of the vulva and extending upwards underneath the mucous membrane of the vagina The growth was hard and circumscribed and was about the size of a walnut It had come without pain, it had been in existence for a few months and had gradually reached the size mentioned The glands in the groin were not affected There was at this time no vaginal discharge, neither was there any bladder or rectal trouble The patient was losing flesh and was becoming anæmic Regarding the growth as of a malignant nature and calling for extirpation, the patient was seen in consultation by a surgeon, who, taking the same view of the character of the tumour as myself, recommended its removal by the knife In due course this was done, the surgeon cutting well wide of the growth and deeply into the tissues The cavity was packed with gauze and the opportunity given for it to heal by granulation Microscopical examination of the growth showed it to be carcinoma

Although the growth was successfully removed, the wound never healed properly It kept discharging pus, notwithstanding frequent surgical dressing The patient left the private hospital five weeks after the operation, but although the cavity had become considerably occluded there remained an open track from which thin pus kept oozing, and as the weeks passed a small ill defined area of hardness could be felt in the depth of the tissues at the site of the operation At first I hoped that this might be cicatricial tissue of a purely reactionary and inflammatory nature As time proceeded the area of ill defined hardness became larger until it reached the size of the original growth, with a line of dense resisting tissue extending up under the mucous membrane of the vagina and also backwards and downwards invading the septum between the vagina and rectum The case was one of recurrent malignant disease and calling for treatment, since the patient was losing control of the bladder and defæcation had become painful and difficult Pain was now a feature of the case The patient's nights were sleepless, she was losing flesh and colour The glands in the groin remained unaffected The other internal organs of the body were healthy

A surgical consultation was again held and an operation recommended but this seemed likely to be severe Since the growth had extended into the external coat of the rectum it meant not only removal of the growth in the vulva and vagina but also of all that lay between the lower part of the vagina and rectum It meant, too, morphine cream containing up to 2 grains to the inch In preparing bases for creams containing crystalloids the viscosity of the cream should be tested after the crystalloid has been added and before the mass is put in the tube, as the addition of even small quantities of a crystalloid considerably alters the viscosity of the cream For instance, a cream which will give in a collapsible tube a perfectly easily measurable semi solid jet will not do so after the addition of hydrochlorate of morphine to it, in the proportion of 1 grain of the salt to 20 grains—i e , 1 linear inch of jet

The application to the patient of these medical creams is so simple as to need no description The inch of jet can be severed from the nozzle of the tube against his teeth, or if he is more or less unconscious it can be dabbed off on the back of his tongue The cap can then be replaced on the tube The bases which I have up to the present used have been kindly prepared by Messrs Roberts, of Bond street, who have shown much ingenuity and perseverance in the matter, and to whom my best thanks are due

Harley-street W

THE TREATMENT OF PERSISTENT DIPHTHERIA INFECTION BY MEANS OF DIPHTHERIA ENDOTOXIN

BY R TANNER HEWLETT, M D LOND F R C P LOND ,
PROFESSOR OF BACTERIOLOGY IN THE UNIVERSITY OF LONDON

IN a former paper[1] Dr A T Nankivell and I detailed results obtained in the "treatment" of persistent diphtheria infections following an attack of diphtheria by means of one or more injections of diphtheria endotoxin prepared by the Macfadyen method Subsequently I recorded another case successfully treated by the method[2] Since then I have treated five more cases One of these was a young medical man a hospital resident, which was not successful, and I have lost sight of him The four remaining cases cleared up after the use of endotoxin Three of these were under the care of Mr A A McAnally, of Eastry, Kent, to whom I am indebted for the notes The following are the details —

Ethel S (11 years), admitted on July 26th, 1914, Edith S (9 years) admitted on July 27th, and Charles S (7 years) admitted on August 6th for mild attacks of diphtheria Between August 10th and Sept. 2nd eight bacteriological examinations showed persistence of diphtheria bacilli A dose of 0 5 c.c of endotoxin was given to Ethel and to Edith on Sept 3rd, but the result was inconclusive six examinations between that date and Sept 18th being sometimes positive, sometimes negative. This endotoxin had been in ampoules for several months and had precipitated somewhat and was probably inert Some more of the same endotoxin which had been kept in bulk was therefore freshly tubed and sent for use A dose of 0 5 c c of this was administered to all three children on Sept 19th, and Charles showed no bacilli on Sept 21st 26th, and Oct 3rd, and was discharged. A second dose of 1 0 c c of endotoxin was given to all three children on Sept. 26th and a third dose of 1 5 c c to Ethel and to Edith on Oct. 4th The bacteriological examinations gave the following results —

	Oct 3rd	6th	8th	12th	15th.	19th.	21st.	24th	26th
Ethel S	+	+	+	+	—	+	—	—	—
Edith S	—	—	+	—	+	—	—	—	—

The last case was that of a young medical man a hospital resident who developed a mild attack of diphtheria on Nov 5th, 1914, was treated with antitoxin and recovered fairly rapidly but in spite of local treatment and change of air bacteriological examinations showed persistence of diphtheria bacilli on Dec 2nd and 23rd, and on Jan 4th, 1915 On this day a dose of 0 5 c c. of endotoxin was given, and bacteriological examinations on Jan 7th 11th, and 17th showed absence of bacilli As a precautionary measure a second dose of 1 0 c.c of endotoxin was given on Jan 11th

Up to date 24 cases of persistent diphtheria infection have been treated with endotoxin Of these cases, in 17 the bacilli disappeared within a reasonable time after the use of the endotoxin, in one (Ethel S) the bacilli did not disappear until 17 days after the last dose of endotoxin, and in 6 the treatment was unsuccessful. As regards the last named, it should be noted that some of them were those first treated, and the doses were smaller than I now employ The treatment I now recommend is to give doses of 0 5 c c , 1 0 c c , and (if required) 1 5 c c at intervals of about seven days In no case has any untoward effect been noticed The endotoxin is injected into the muscle of the upper arm or back, and gives rise to some pain, tenderness, and swelling, lasting a day or two, at the site of injection, and occasionally to some malaise, rash, and rise of temperature Thus in 75 per cent of the cases the use of the endotoxin has been followed by disappearance of diphtheria bacilli, and I think the results are such as to warrant an extended trial of the endotoxin in the treatment of these troublesome cases of persistent diphtheria infection

AN X RAY DIRECTOR FOR THE REMOVAL OF FOREIGN BODIES IN THE TISSUES[1]

BY W IRONSIDE BRUCE, M D ABERD , D P H.,
PHYSICIAN TO THE X RAY AND ELECTRICAL DEPARTMENTS OF CHARING CROSS HOSPITAL, ETC

IT is possible by means of X ray to supply information as to the exact position of any foreign body imbedded in the tissues—a fact which was first demonstrated by Sir James Mackenzie Davidson, his method being generally admitted to be at the present time most reliable and accurate Since then other methods have been devised which make for ease of application with accuracy sufficient to deal with foreign bodies of some size in the trunk and limbs The real difficulty, however, rests in the application of such measurements by the surgeon at the time of operation, and for this reason I wish to draw attention to a piece of apparatus which, if it is at all practical to employ, I believe will lead to the successful removal of foreign bodies from any of the tissues, provided such are accessible from a surgical point of view The principle involved was made use of some seven years ago, and I produced at that time an apparatus, which (though quite successful) was never developed because it was so complicated and difficult to apply, moreover, the question of foreign bodies at that time was not urgent

The presence of foreign bodies in the tissues is now a matter of the greatest importance, and from what I have seen and heard about their removal there would be no objection to the employment of a more or less elaborate apparatus even if costly, provided that such were a decided advantage to the small contract rate having previously been arranged. In the first week in November, however, a portable Thresh's steam disinfecting apparatus was supplied to the division, through the second army, since when no difficulty has been experienced in the disinfection both of clothing and blankets

---

[1] A paper read before the Medical Society of London on Jan 25th 1915

Appended to the article on lice by Professor Shipley, referred to above, was a series of suggestions drawn up jointly by Professor Nuttall and himself, in which the use of paraffin or petrol was advocated for the extermination of lice Doubtless these substances would be perfectly efficacious for the desired purpose, but their use was not attempted owing to the possible danger, not unlikely to be incidental to the use of substances of so inflammable a nature by large numbers of men. As a matter of fact, the simple and inexpensive method which has been employed by us over a period of several months has proved so successful that no necessity has arisen for a trial of other means of treatment It may perhaps be mentioned that a number of copies of our memorandum have been distributed in reply to requests from medical officers of health and medical officers in charge of troops And in view of the fact that trouble due to the prevalence of lice has been experienced in other camps in various parts of the kingdom, the medical officer to the Local Government Board, and other members of the Army Sanitary Committee, suggested that a useful purpose might be served by the publication of a method which has been found so efficacious under service conditions

A SIMPLE METHOD OF ADMINISTERING DRUGS UNDER WAR AND OTHER STRENUOUS CONDITIONS

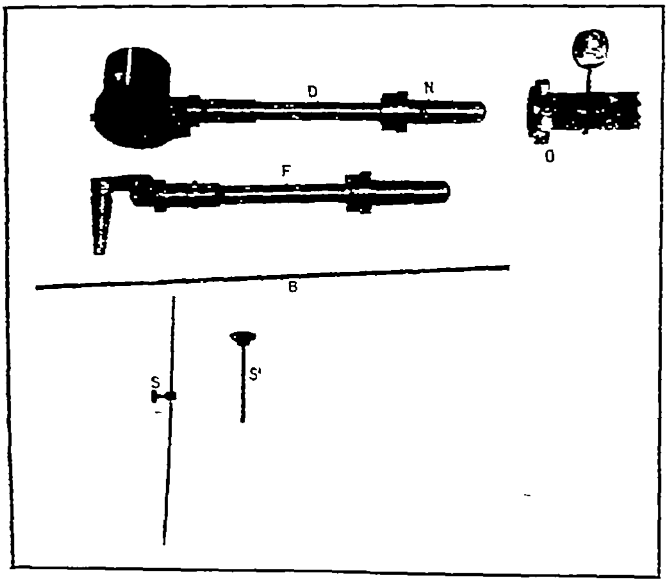
By F W TUNNICLIFFE, M D LOND ,
OUT PATIENT PHYSICIAN KING'S COLLEGE HOSPITAL LECTURER IN THERAPEUTICS AND PRACTICAL MEDICINE IN KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.

A FEW days ago I was asked to design a medicine kit to be used by an officer in the trenches for the treatment of ailments amongst his men It appears that, generally speaking, the services of a medical man are not available, or at any rate may not be available, under the above conditions The ailments occurring amongst the men during their occupation of the trenches, which I understand is now about four days can perhaps, with one exception, be aptly included under the general term minor medicine It was put to me that appropriate medicinal treatment might often prevent a man going on the sick list, or at any rate mitigate the discomfort suffered by him, if, as is invariably the case, he made up his mind to endure much rather than report himself sick. It is not my intention in this note to deal with trench maladies, although a communication upon this subject might be most interesting and helpful The point, however, which is to be insisted upon is that it is most important to have at hand in the trenches a means of relieving urgent pain The seriously wounded have often to remain a considerable time in the trenches before they can be removed to the rear, and with the hours of darkness getting shorter as the season advances this time will certainly be prolonged During this period they suffer most distressing pain, which, both from the restlessness caused by it and its general effect upon them, is likely to make them less capable of enduring the transit and treatment to which they must subsequently be submitted, it is also a source of extreme distress if not of actual demoralisation to their comrades For such cases an active anodyne in massive doses is urgently indicated and the form in which it is available is not a matter of indifference

The conditions obtaining in the trenches render hypodermic injections or rectal injections practically impossible The absence of water makes solution of any solid preparation and subsequent volumetric measurement difficult, in fact, I am told also practically impossible Tabloids require a manipulation on the part of the giver and a capacity for swallowing on the part of the patient which cannot always be relied upon as obtaining The best method of which I know at present is the inclusion of the drug to be given in a gelatine or gum stick or in a thin gelatine sheet In the first case a certain length of the stick is cut off with a penknife and put in the patient's mouth, in the second, an area of sheet is cut off with scissors and also placed in the patient's mouth, length of stick and area of sheet corresponding to a given dose Muddy hands and indiscriminate knives render even such simple manipulations as these neither as easy nor as clean as they sound Almost the same objection applies to perles, capsules, palatinoids, wafers, &c Further, since some of our troops are fighting in snowstorms in Flanders, and others under a practically tropical sun in Egypt and elsewhere, the melting point of the drug base must be considered

The method which I have employed, and which I think, is capable of wide application, is to prescribe the drug to be given in a semi solid aromatic base and to enclose the mass in a collapsible tube such as is generally used to contain remedies for external application. The base must be sufficiently viscid to enable a continuous semi solid jet of substance to be exuded from the nozzle by pressure at the bottom of the tube By varying the composition of the base in glycerine, bismuth base, agar agar, &c , all climatic conditions can be allowed for There are many kinds of collapsible tubes on the market, those are specially to be recommended in which the screw cap is permanently attached to the neck of the tube, in these the cap cannot be lost With a given base the weight of a given length of jet is practically constant, and by this means an accurate dosage can be obtained The medicinal creams which I have had made so far all have the same dose—viz., 1 linear inch of the exuded jet An inch can easily be measured against the last joint of the thumb, and indeed can practically always be accurately guessed I made several experiments with different kinds of tubes and was at first greatly tempted to make use of those tubes of which there are many on the market, with keys at the bottom, I thought that accurate dosage could be obtained by turning the key through definite arcs This method is, however, quite fallacious owing to the inconstant calibre of the tubes throughout their length As a constituent of the base I prescribe some aromatic substance which promotes salivation and thus reflexly stimulates swallowing So far as I am aware any drug, crystalloid or otherwise, or any first dressing of wounds, except hydrogen peroxide, can be administered in this form and in adequate concentration I have prepared, for instance, a chlorodyne cream containing up to 30 minims to the inch and a

FIG 3



Illustrates the fluorescent screen D showing the cross wires to indicate the screen centre a point corresponding exactly to the centre of the guide which is shown marked F The special joint N is constructed so that it is impossible that any change of position occurs both the screen and guide fitting tightly the same socket and locked in position by the pin P There is a brass collar O which is screwed to the arm and is provided for the purpose of easy removal of the screen and guide from the tight fitting joint The blunt graduated director is marked B and the sharp one with its sheath is shown at S S

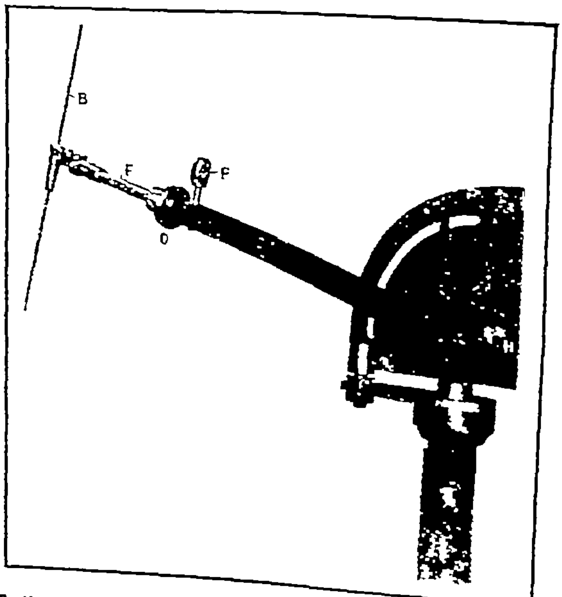
brought in more or less close relationship with the subject lying on the surface of the couch (sliding joint in position shown in Fig 1E) Since the box and X ray tube are freely movable, and the upright and cross arm are firmly attached to it, the screen will maintain the same relationship to the X ray tube in whatever position it is placed An X ray tube can be so arranged that only the actual central radiation is used, and under these circumstances the shadow of a foreign body as seen in the screen indicates the exact point in space below which that body lies In other words, if the X ray tube maintains always the same relationship with the centre of the screen, the central radiation only being used, the shadow of the foreign body seen in the centre of the screen indicates that the body must lie in a line drawn between the tube and the screen centre In this couch these conditions are easily complied with, for the central radiation is adjusted to correspond with the screen centre, and thus if the shadow of the foreign body is brought central in the screen it mus lie below the screen centre in a line between the X ray tube and that point

The tube box is capable of being firmly fixed in any determined position to the couch by simply pressing a lever, and consequently during observation when the shadow of the foreign body has been arranged in the centre of the screen, the whole—box, tube, upright, and cross arm—can be firmly fixed to the couch by making use of this lever When this is accomplished the advantage gained is that we have in the screen centre a fixed point below which the foreign body lies The screen is detachable from the cross arm (at the specially arranged joint seen in Fig 3N) and in its place can be substituted a sterilisable metal guide carrying a director (seen in Fig 3F), the point of which is arranged to correspond exactly with the centre of the screen, which has been removed The guide permits of movement of the director, only in the direction corresponding to the central radiation—that is, in the line between the screen centre and the X ray tube, which is, in fact, in the vertical plane If the director running through the guide is advanced through the tissues its point must impinge against the foreign body, for owing to the whole construction being rigid any deflection from the proper plane is impossible The advantage gained by this procedure is evident, for the surgeon is provided with a director which will unfailingly lead down to the foreign body, permitting him to deal as he pleases with the intervening tissues

The guide and director are sterilisable, so can be safely handled during the operation A joint is provided in the cross arm to allow of the director being lifted out of the way and returned in exactly the same position when wanted (Fig 4, cross arm lifted out of the way Fig 2, returned in identical position—joint at H) The X ray observer from the moment the observation is made hands over the whole apparatus to the surgeon, and takes away all his part of the construction, so that no unsterilised part is brought near the area of operation

Two forms of director are provided, one blunt and graduated (Fig 3B) so that the depth discovered by previous localisation can be made use of, the other sharp in the form of a needle (Fig 3S) to be introduced in suitable cases into the tissues until the point comes in contact with the foreign body When using the sharp director a telephone can be attached to announce the contact of the point of director with foreign bodies The blunt director is provided for use in cases in which it is not advisable to introduce the sharp instrument For example, in

FIG 4

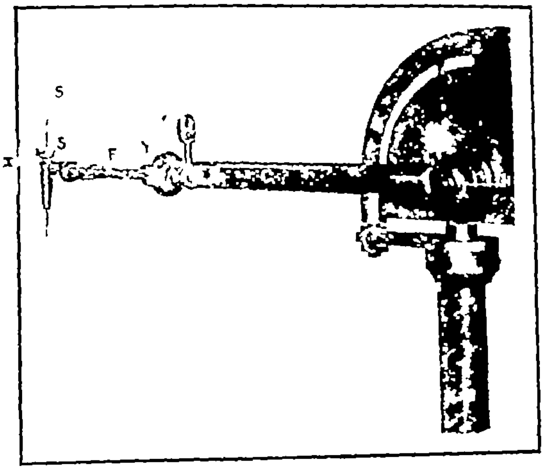


To illustrate the cross arm raised out of the way at the joint H, the guide F and blunt director B being attached The arm can be replaced as shown in Fig 2 without any change in the position of the guide or director surgeon Accordingly the original design has been altered, elaboration remains, but the actual application is simplicity itself

On proceeding to deal with a foreign body in the tissues, which has been localised previously by one or other of the methods devised, the surgeon is confronted by the following difficulties The marks on the skin are useless once the superficial incision is made, the knowledge of the depth at which the foreign body lies give him little help, since the tissues vary much in thickness, and, lastly, the foreign body, which is said to lie directly below a certain point indicated on the skin—a statement correct only so far as one plane is concerned—is missed, for it is often impossible for anatomical and other reasons to maintain the plane indicated during operation, some deviation being made and the direction lost

To deal with these difficulties the apparatus which I am about to describe has been constructed The first principle involved is the necessity that the position of the limb or trunk at the time of operation should be the same as that at the time of observation This can only be accomplished satisfactorily by a combination of X ray couch and operating table, as illustrated in Fig 1, so that when under the anæsthetic the subject is placed in the position previously selected by the operator, and, having been firmly fixed in this position by means of sandbags and straps, the X ray observation is made and the operation immediately proceeded with

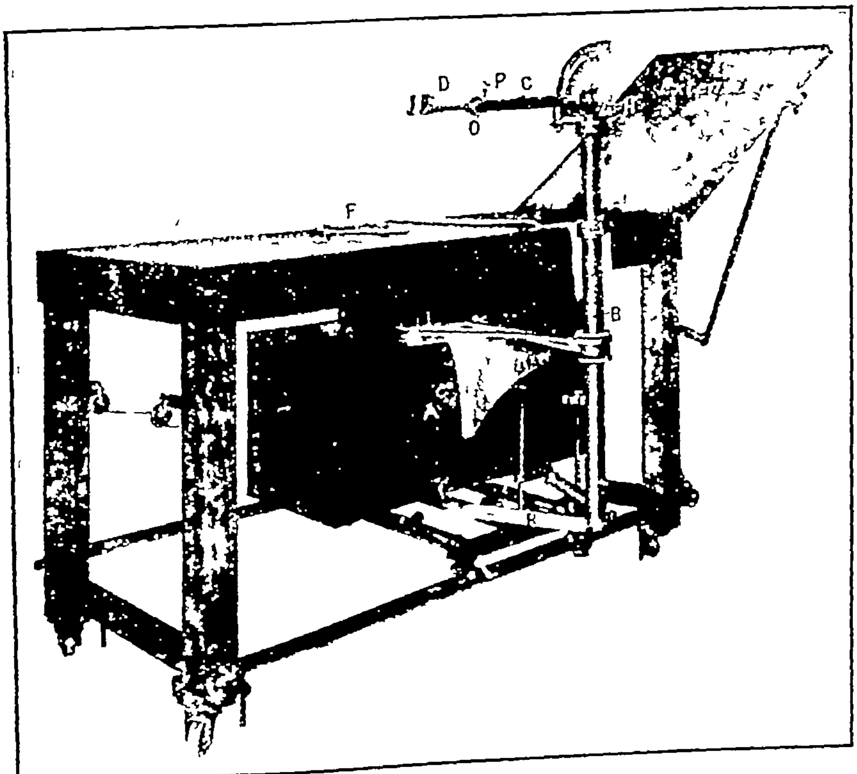
FIG 2



Illustrates the cross arm C attached to the upright B showing the sterilised guide F and sharp director S attached The cross arm C can be raised by movement permissible at the joint H which is constructed so that the arm is returnable into exactly the same position without difficulty From the point X to Y the arm is sterile when in use by the surgeon

Only one observation should be necessary, but it might happen that accidental movement of the subject occurs, in which case there is no reason why further observations should not be made at any stage of the operation, since only a few minutes are necessary for such a proceeding The use of the fluorescent screen is essential, so arrangements have been made to enable this to be done in daylight, or bright artificial light, the X ray observer wearing dark glasses for some time beforehand to accustom the eyes to darkness, and an effective fluoroscope being attached Secondly, the provision of a guide for the operator other than a mark on the skin It is possible to arrange in connexion with the couch a vertical guide which corresponds exactly with the direction of the radiation To accomplish this, below the couch in a box (Fig 1A), which can be moved in any direction freely and easily, we have placed the X ray tube, and springing from this box is a strong and rigid upright (Fig 1B), to which is attached a cross arm (Fig 1C) projecting over the couch, all these parts being firmly fixed one to the other, and moving as one piece At the extremity of the cross arm is attached a small circular fluorescent screen (Fig 1D) there being provision for lowering or raising the cross arm so that this screen may be

FIG 1



Shows the construction of the couch and operating table an extension in the form of a flap (attached to one end) allowing for the accommodation of the patient in dealing with the lower limbs The couch is provided with a wooden top which can be kept clean and will not absorb fluid The box containing the X ray tube is marked A and springing from it supported by the right brackets marked B B is the upright marked B, to which is attached the cross arm marked C All these parts are firmly fixed one to the other and the box with its attachments upright and cross arm can be moved freely and easily along and across the whole length and breadth of the couch The small circular fluorescent screen attached to the cross arm is seen in the position marked D There is a sliding joint marked P provided (in the upright) for lowering and raising the screen so that it can be brought close to the surface of the body On the couch is seen lying a strap for securing the subject and the sterilisable director and guide F

ROYAL SOCIETY OF MEDICINE

SECTION OF PSYCHIATRY

The Application of Physiology to the Study of Mind in Health and Disease

THIS section held its opening meeting of the session on Jan 26th, Dr F W MOTT, the President, being in the chair

The PRESIDENT took for the subject of his address the Application of Physiology to the Study of Mind in Health and Disease, and his theme was the importance of the ductless glands in the human economy, especially their influence upon growth and later in life, upon reproductive activity and integrity He quoted with approval Maudsley's contention as to the necessity of attempting the objective method in the study of mind, for as Maudsley said, that which a just reflection taught incontestably the present state of physiological knowledge illustrated practically, and Maudsley contended 40 years ago that no psychology could endure which was not based upon physiological investigations, though physiology could not expect for many years to furnish the complete data of a positive mental science Physiology, however, had now made great advances, and in no sphere was this more notable than in the biochemistry of the ductless glands and the influence of their internal secretions on the bodily functions, an addition due, in great measure, to English physiologists It was very desirable to apply this knowledge to the study of psychiatry In Maudsley's work on the "Physiology of the Mind" the hormone theory was anticipated, for he said that the overmastering feelings during pregnancy and those arising from puberty could not be explained in consciousness, and that there was reason to believe that each internal organ of the body had its representative control in the supreme cerebral centre The functional development of the reproductive organs occurring at puberty effected a complete revolution in the mentality of the youth, and he now became susceptible to impressions which were previously a matter of indifference to him, he was now the subject of aimless longings and obscure impulses, and altruistic feelings began to germinate and he appreciated what others had done for him in the matter of care and nurture These feelings were not present in cases in which the reproductive organs were removed before puberty The evolution of the sex glands was also important in regard to disease. Nature was not mindful of the individual, only of the species, and the sexual was the strongest of all the impulses The desires had their source in the unconscious life It was a common saying that love was blind, yet it also added a precious seeing power to the eye which was necessary to materialise the biochemical stimulus and effect the continuation of the species The language of love was universal, it could not be concealed when it existed nor feigned where it did not exist Yet in the present condition of civilisation this was the impulse subjected to the greatest amount of repression Insanity was especially common at two periods of life in adolescence and at the involutionary period. He asked whether it should be assumed that the mental disorder of the true insanities or psychoses, even those which terminated in dementia could be explained by any structural changes in the brain, or should it not rather be believed that they were due to disturbance of the physiological equilibrium and of the internal secretions of the ductless glands in many instances acting on a weak inheritance' The interstitial gland structure of the sexual organs functioned independently of the genetic gland structure, and functionally correlated with the sexual glands were the thyroid the parathyroid the hypophysis the pineal gland, the cortical portion of the suprarenal gland the thymus, and probably also the islands of the pancreas For a proper study of this subject there should be a systematic examination of all these glands in health and disease at all age periods and in persons with and without mental disorder He had obtained objective grounds for the association of aberrant mental conditions with disease of ductless glands in three cases of myxœdema In the thyroid gland there was marked increase of lymphoid and fibrous tissue, and a complete absence of colloid material in one, and a great reduction in the others There was an increase of colloid material in the pars intermedia of the pituitary gland, and the central nervous system showed marked chromolytic changes in the nerve cells, affecting in a grave manner the autonomic bulbar system There was an association of the myxœdematous syndrome with acute psychosis During pregnancy the thyroid gland increased in size, and there was a marked colloid increase in the follicles, a similar increase took place during menstruation and at the climacterium In pregnancy, too, there was an increase in the parathyroids There was also a large increase in the lipoid cholesterin content of the adrenal gland, and these cells were, structurally and chemically, closely allied to the cells of the Graafian follicles The thyroid gland might be of ordinary size yet contain very little gland substance, hence it was necessary to examine microscopically An interesting case was that of a married woman, aged 57, whose speech was said to have been slow, and who had indistinct tremors of face, hands and tongue, her memory was impaired, and she had no idea of time or space, she had attempted suicide prior to admission She became so demented that she was considered to be a case of general paralysis Post-mortem examination, however, showed that she had not had general paralysis The sella turcica was very large, the glenoid processes absorbed, the pituitary was twice the normal weight, and the thyroid gland very atrophied and fibrotic There was an infantile uterus, and the left ovary was destroyed by old salpingitis, the right one was atrophied and damaged Probably the patient had had gonorrhœa early in life An increase in the size of the pituitary gland might have an important bearing on the production of mental symptoms, if the cerebro-spinal fluid served as the lymph of the brain, as he believed, excess of the colloid which irrigated the neural spaces might have an important influence on the functions of the organ of mind, but more work was required to remove this from the sphere of imagination. The ovaries of women suffering at an early age from insanity, and dying in early or late adolescence, had been found at the necropsy to be fibrotic Dr Laura Forster had made a series of examinations of ovaries in cases of dementia præcox. Those of subjects who had reached the age of 30 showed signs of early involution and great scarcity of Graafian follicles, also in cases of *manie dépressive* there was a diminution in those follicles But the value of these findings was greatly lessened by the fact that in a woman who died from heart disease without any mental trouble there was a like reduction Still, Dr Forster's work was highly suggestive With regard to the pineal gland, it had been shown that tumours of the pineal gland occurring in very young people had been associated with precocious development of the sexual functions and the secondary sex characters It had been thought that the pineal gland might exert some inhibitory function on the development of secondary sex characters As to the suprarenals, it had been known since the time of Addison that this gland was essential to life It had been found that the emotion of fear exercised such an effect as to liberate adrenalin in excess into the blood Elliott had dealt in an illuminating manner with this subject in the Sydney Ringer lectures The cortical cells of the suprarenal gland were of great importance in the development of the body during its early existence, especially in regard to the brain. And it was of great importance in relation to the development of spermatozoa and was increased in the pregnant woman, probably the material was necessary for the growing embryo Adenoma of the cortex of the suprarenal gland had been found associated with precocious sexual development in both males and females There was also, in the animal series, a correlation between the size of the brain and the amount of adrenal cortex, the cells in its cortex were the source of supply of the lecithin and cholesterin required for the enormous growth of the cerebral hemispheres in early life In conclusion, Dr Mott said that though the subject of biochemistry was still in its infancy, it promised most hopeful results

Dr J G SOUTAR (Gloucester) in proposing a vote of thanks to the President for his address, pointed out how much the clinical alienist was indebted to those who like dealing with the abdomen by using this device it is possible to open the cavity, the guide and cross arm being lifted out of the way to facilitate this part of the operation, retract the parietes, bring the director again into place, and gradually advance its point to the depth previously ascertained, dealing with intervening structures as they present themselves

It is obvious that before using such an apparatus as I have described an ordinary X ray examination should have been conducted to settle roughly the position of the foreign body and enable the surgeon to decide upon the line of operation, which having been done a surface localisation should be made in order that the depth of the foreign body may be gauged and its position roughly indicated on the skin, to assist in its subsequent observation with the small screen provided in the X ray director

In conclusion, I wish to express my indebtedness to Dr W Lindsay Locke for many valuable suggestions and for the interest he has taken in our endeavour to get the apparatus as mechanically perfect as possible

Chandos street W

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

LOSS OF MEMORY DUE TO EXPOSURE

BY H J COOPER, M A, M B CANTAB, M R C S ENG, L.R C P LOND

THE following case seems worthy of record, as apart from the patient being one of the survivors of the ill fated H M S *Formidable*, it seems that a scientific interest must be attached to the mental condition following the exposure and apparently caused by it, as there was no evidence of injury having been sustained Similar cases are known to occur after concussion of the brain, but so far as I know none have been recorded as due to exposure

The patient, a boy aged 18, left the ship in one of the boats about 2 A M on Jan 1st scantily clad, and was exposed to the full force of a very violent southerly gale till 11 P M the same day The boat was constantly swept by the seas and all the occupants were the whole time drenched to the skin, the boat being frequently half full of water and only kept afloat by constant baling When brought ashore the patient was quite unconscious as were several other occupants of the boat His pulse was very small and intermittent, and the respirations were very feeble He could not be made to swallow, so hypodermics of strychnine and brandy were administered, his breathing improved but became rather stertorous At 4 A M on Jan 2nd he was still very cold in spite of hot water bottles and friction, and the pulse was still very feeble By 9 A M he had recovered consciousness to some extent but seemed very dazed and passed everything under him in the bed, and this occurred for three or four days His temperature at 2 A.M on Jan 2nd was 100 4° F, and in the evening it was 101°, subsequently it ran a normal course

By Jan 9th the patient was up and walking about but could remember nothing about the incidents in the boat or how he got into it, and had only a vague recollection of the explosion At this time he seemed to have no sense of locality and lost his way about the small hospital He also appeared lethargic, though his companions stated that he was usually of a very lively disposition On the 12th he was much better and could remember some of the incidents in the boat, such as one of the crew going mad There was nothing abnormal to be found with the exception of the hands and arms being unusually blue The pupils were equal and the knee jerks normal There was no albumin in the urine

Though there were six other men who were quite unconscious when landed, some of them, like this patient, not recovering consciousness till many hours after, none of them showed any loss of memory for events which had taken place prior to their becoming unconscious

Lyme Regis, Dorset

SPEEDY ENUCLEATION OF THE EYE

BY JOHN FURSE MCMILLAN, M.R C S ENG,
CAPTAIN ROYAL ARMY MEDICAL CORPS (RET)

IN these times when celerity is the order of the day it may not be amiss to record a case of enucleation that occurred in practice amongst natives in a clinic at Ferozepoor, the Punjab The note may be of service having regard to circumstances of war

The patient was a girl between the age of 5 and 6, suffering from the effects of contagious purulent ophthalmia of the left eye The patient having been anæsthetised, I affixed the stop spring speculum and with a hook drew forward and depressed the eyeball, when I was struck by the cramped position of the parts, and so, after having cut round with scissors the conjunctiva above the horizontal equator, I punctured the ball and allowed the vitreous to escape Then with ease and speed the muscles of the eye were severed, the membranes of the ball were divided at the longitudinal equator, and next carefully trimmed to the eighth of an inch around the optic nerve There was little or no hæmorrhage A pad of boracic wool was inserted, and bandage applied. The next morning the wound had almost completely healed by first intention, and at the next visit it was found that the child was so far thought to be completely recovered as to be taken back by her father to her village

Celerity here was the main point As regards the danger of sympathetic ophthalmia the risk would appear a minimum, though one would view with caution any tampering with the optic nerve Let us suppose that the wound does not unite by first intention, as is possible under the conditions of warfare, then it would appear obvious that there is less likelihood of inflammation of the stump than if the optic nerve had been severed In puncture of the ball the time taken is three and a half minutes, in non puncture five minutes or over

ROYAL SANITARY INSTITUTE —Dr M S Pembrey lecturer on physiology Guy's Hospital and late member of the Advisory Board Army Medical Service will open a discussion on Tall *versus* Short Men for the Army at the Royal Sanitary Institute, 90 Buckingham Palace road London S W on Tuesday next Feb 9th at 7 30 P M The chair will be taken by Surgeon General Sir W Launcelot Gubbins K C B

We have referred to only those portions of the work which have been revised or which are to be found for the first time in this edition. Dr Brend may be congratulated on the way in which he has modernized this excellent text book, and we can cordially recommend it both to medical practitioners and students. Barristers also would find it of considerable assistance as a work of reference.

The Blood. A Guide to its Examination and to the Diagnosis and Treatment of its Diseases.

By G. LOVELL GULLAND, M.A., B.Sc., M.D. Edin., F.R.C.P. Edin., Senior Lecturer on Clinical Medicine in the University of Edinburgh &c., and ALEXANDER GOODALL, M.D. Edin., F.R.C.P. Edin., Assistant Physician to the Royal Infirmary &c. Second edition. Edinburgh and London: W. Green and Son. 1914. Pp. 384. Price 15s. net.

WE are glad to welcome a second edition of this book within a relatively short time since its first appearance. Its general scope is not much altered, but it has been brought up to date and has received considerable additions in the process. For the benefit of those who are not already acquainted with the volume we may point out that the first 53 pages are devoted to methods of examination—counting, staining, and so forth, then follows a description of the formed elements of the blood, with their sources and their variations in different animals and different conditions, next comes a detailed account of the various disorders of the blood, or so called blood diseases, and the remainder of the volume treats of the condition of the blood in other affections and of the parasitic organisms which are found in it.

Among the novel matter appearing in this edition we may mention the discussion of von Schilling Torgau's views on the structure of the erythrocyte, according to which these cells are supplied with a nucleus, a centriole, and two peculiar intracellular bodies the glassy body and the capsule corpuscle, giving the red cells a much more complicated constitution than is generally recognised. The authors do not discuss or criticise these views, so that we do not gather how far they accept them. We welcome their plea for the retention of Ehrlich's original classification of cases of leukæmia into lymphatic and medullary, as opposed to complicated subdivision based on special forms of leucocytes found to be present, although mixed forms must be admitted. An appendix is devoted to the question of splenectomy in pernicious anæmia—a procedure which the authors do not regard favourably, as the seat of the trouble is probably in the bone marrow and not in the spleen. Here as elsewhere the judgment expressed is prudent and commendable.

The book is well got up and well illustrated.

Elements of Pharmacy, Materia Medica, and Therapeutics.

By Sir WILLIAM WHITLA, M.A., M.D., LL.D. Tenth edition. London: Baillière, Tindall, and Cox. 1915. Pp. xii.-630. Price 9s. net.

THE appearance of the tenth edition of a text book bearing on the title page the statement that it is the forty second thousand would almost warrant a reviewer in considering that no detailed criticism was necessary. In a brief preface however the author states that the advent of the new British Pharmacopœia has necessitated changes on every page, and that the present volume may therefore be regarded as a new book. Those familiar with former editions need feel no alarm at this broad statement. The general arrangement of a wealth of material remains as before, the novelty consists in the assimilation of the changes which must be made if the book is to be brought into harmony with the new standard. The introduction of the metric system is responsible for many of the changes, much space is devoted not only to a reproduction of the tables from the Pharmacopœia, but also to several more detailed tables which will save time and calculation.

As in former editions, the author has shown an admirable discretion in separating from the official monographs just those details which are likely to be of service either to the student or the junior medical practitioner, he omits all reference to standards of purity and to arsenic limits and lead limits. On the other hand, there are many useful hints relating to incompatibility and to convenient methods of securing suitable combinations of new and old remedies. The therapeutic section has been carefully revised, and there is abundant evidence that Sir William Whitla has keenly scanned all recent therapeutic advances. The section on non official remedies, which extends to over 130 pages, contains information relating to very numerous drugs, nearly all protected by trade names, and in many cases to be regarded as still *sub judice*. In referring to this section, students should note the care with which the author has given the names of those responsible for many of the observations, he does not always indicate that he has himself confirmed the experiences of others.

The prescriptions in the section on therapeutics will serve as good examples to young prescribers, but it may puzzle them to ascertain what system of abbreviation has been adopted. On p. 467, in consecutive lines will be found Tinct. and Tr., and Spirit and Spt. are of frequent occurrence, nor is there any apparent reason why Syrupi should generally be written in full and sometimes be contracted to Syr. These little inconsistencies do not materially detract from the general high standard of the work for its special purpose. It may be anticipated that it will receive the cordial acceptance accorded to former editions.

The New Parent's Assistant.

By STEPHEN PAGET. London: Smith, Elder, and Co. 1914. Pp. 119. Price 3s. 6d. net.

THE charm of Mr Stephen Paget's previous essays had led us to regard a new volume of essays by him with the feelings of a schoolboy towards a hamper from home. "The New Parent's Assistant," while consisting like his previous books of a number of individual essays, differs from them in the fact that all the essays have relation to one subject—viz., the bringing up of the child as a sound organism, physically, mentally, morally and religiously. Mr Paget's method of assisting the parent differs fundamentally from that of Miss Edgeworth, from whose "Parent's Assistant," needless to say, he has adapted the title. Miss Edgeworth wrote down stories told to occupy the children's attention and so keep them interested while insidiously training them on the moral lines that were the ideal of an age of sentiment. Mr Paget deems it a more effective method to keep the parents interested while equally insidiously imbuing their the President, were working to establish principles on which progress could be made in the treatment of mind disease

Sir George Savage seconded, *remarking* that the President was such a successful pathologist because he did not think the science was to be learned simply from dead matter

---

Ulster Medical Society —A meeting of this society was held in the Pathological Laboratory of the Queen s University of Belfast on Jan 21st Dr J S Morrow, the President, being in the chair —Sir John Byers gave an account of a case of severe Pre eclamptic Toxæmia successfully treated by the Stroganoff method A very careful chemico-physiological analysis of the urine, made by Dr John Gibson, was brought forward —Professor W St C Symmers read a short paper giving an account of the lesions produced in a Soldier s Skull by the Accidental Discharge at Short Range of a Modern Rifle —Dr T S Kirk read a short note on a case of Fat Embolism following Fracture of the Femur —Dr T Houston read a paper on Bacteriological Diagnosis —Dr W W D Thomson read notes on the investigation of a case of Chronic Interstitial Nephritis with an unusual degree of urea retention, and on certain peculiar crystals found in the cerebro-spinal fluid in a *case of septic meningitis —Sir Alexander Dempsey* showed a Tumour of the Suprarenal Gland and a Cancer of the Body of the Uterus —Mr A. B Mitchell showed a Carcinoma of the Penis, an Ulcer of the Stomach Resected, and a Gall bladder containing Gall stones —Mr R J Johnstone showed a specimen of Abdominal Pregnancy, a Tumour of the Transverse Colon which gave considerable difficulty in diagnosis, and a very large Fibroid of the Uterus —Mr A Fullerton showed some Renal Calculi.—Mr Howard Stevenson showed a specimen from a case of Acute Hæmorrhagic Pancreatitis —Dr C G Lowry showed a Fibrocystic Tumour of the Ovary which caused intraperitoneal hæmorrhage, and a Calcified Tuberculous Pyosalpinx from a woman aged 62.—Dr G A Hicks showed specimens of Tuberculous Fallopian Tubes and a case of Tubal Abortion —Dr Thomson showed a Rapid Method of Preparing an Autogenous Acne Bacillus Vaccine, a case of Pseudochylous Ascites in which Lactescence was due to Globulin, and Blood films illustrating (1) blood changes in von Jaksch's disease and (2) marked mitotic changes in the megaloblasts in a case of pernicious anæmia —Mr S T Irwin showed a breast with an Adenoma and Multiple Cysts —Dr T S S Holmes showed a Kidney with Pyonephrosis —Specimens were also shown by Professor Symmers and by Sir John Byers —Full discussions followed the reading of the various papers

Harveian Society of London —A clinical meeting of this society was held at the Paddington Green Children's Hospital on Jan 28th, Dr Edgar G Bulleid, the President being in the chair —The following cases were shown —Dr Leonard G Guthrie Juvenile Tabes with Optic Atrophy in a boy suffering with congenital syphilis —Dr Corry (for Dr Guthrie) Enlargement of Thyroid Gland in a child aged 6 —Dr G A. Sutherland (1) Tuberculous Peritonitis, showing a very well marked von Pirquet's reaction, and (2) Congenital Pyloric Hypertrophy —Dr R H Miller Aortic Regurgitation of recent rheumatic origin in a child —Dr W H Willcox *(1) Renal Calculus in a man who referred* his pain to the side opposite to the kidney in which the stones were shown by X rays to be situated, and (2) Toxic Jaundice due to poisoning by tetrachloride of ethane, in an employee of an aeroplane factory —Dr Frederick Langmead Muscular Fibrosis in a girl aged 5 Had been under observation since 5 weeks of age for scleroderma, upon which the muscular condition had been superimposed.—Mr H W Perkins showed numerous Pathological and Microscopic Specimens

Bradford Medico-Chirurgical Society —A meeting of this society was held on Jan 19th Dr Arthur Manknell being in the chair —Dr William Mitchell gave an X Ray Demonstration a large variety of plates being shown. Of special interest were a series of plates showing multiple fractures from a case of osteomalacia and also a series showing the stomach after a bismuth meal in various gastric diseases —Mr W H. Hooton showed a radiograph of both kidneys in which were huge stones This case was said to be unique as being the largest bilateral renal calculi on record —Dr A. Rabagliati read a paper on the Functions of the Connective Tissue After minutely describing the anatomy of the connective tissue he laid great stress on the continuity *of the areolar tissue throughout the body,* and pointed out that this was of great importance in relation to the spread of infections He then proceeded to elaborate a theory that the connective tissue cells were organs of sensibility inasmuch as they were the organs which received sensations while the nervous cells and tissues carried out their function of interpreting these sensations

Forensic Medicine and Toxicology

By J Dixon Mann, M D St And, F R C P Lond Fifth edition Revised and enlarged by William A Brend M A. Cantab M B, B Sc Lond Barrister at Law Lecturer on Forensic Medicine and Toxicology, Charing Cross Hospital London Charles Griffin and Co, *Limited 1914 Pp 737 Price 18s*

This volume is well known, and for advanced students no better text book can be found In the present edition Dr Brend, who is responsible for its production, recognising the thoroughness and accuracy which always characterised the work of the late Professor Dixon Mann, has left the main features of the book as far as possible untouched By numerous additions he has brought it thoroughly up to date

An account of the Mental Deficiency Act has been included The classes of patients who are deemed to be mentally defective within the meaning of the Act are set forth, and the requirements as to the making of orders are explained A short account is given of the Workmen s Compensation Act, 1906, and some instructive *remarks are made on the* difficult question of "malingering" It is pointed out that the real fraudulent malingerer is relatively rare in comparison with the great number of claims which are preferred under the Workmen's Compensation Act and the National Insurance Act Dr Brend recognises four types of cases of fraudulent claim (1) *persons* who have no affection or injury of any kind, (2) those who are suffering from lesions deliberately produced, (3) those who represent old standing disease or injury to be the result of a recent accident, and (4) those who are suffering from the effects of an injury or disease not of a serious character, and who consciously and fraudulently exaggerate their symptoms We consider this a good practical classification, and medical examiners may simplify their ideas by acting upon it *Many cases of suspected* malingering present great difficulties, but the introduction of medical referees has exercised a restraining effect in the prevention of fraudulent claims

In discussing drugs which have been adopted for the purpose of procuring criminal abortion, attention is rightly drawn to the use of lead, most frequently in the form of pills made from diachylon The practice appears to have originated in the Potteries, where women working with lead would be likely to discover its effects in this direction In the part of the book dealing with toxicology an account of the law relating to the sale of poisons has been added, and recent work connected with poisoning by veronal aspirin, carbon monoxide lead ferro silicon, unsound meat, and other substances has been included *the technical side of electricity far in advance of* that of the average medical man. In making the above criticism we are not to be understood as implying that there is no place for such a book as this On the contrary, it fills a real want, and will be of the greatest value to all those who are taking up those branches of medical work where electrical appliances are largely used To many such the technical and physical problems involved are a serious difficulty from the fact that so few medical students take any interest in electro physics beyond the minimum required to pass a preliminary examination, and what little they learn they take no pains to remember in after years They will find, however, in this volume a means by which they can recover many lost opportunities, and for answering the technical and physical questions that are continually suggesting themselves the book will be found most useful. Where explanation offers any difficulty the author has made use of diagrams to make the description more clear, a great improvement on the mere use of an illustration of the finished apparatus from an instrument maker s catalogue, which teaches little or nothing

The second part of the book is devoted to X ray appliances including a very useful chapter on the management of the X ray tube, a subject none too well *understood* by many of the radiographers suddenly called into being by the crisis through which the nation is now passing
